\* Second estimate. — (1) Including Sakellaridis.

By a decree of the Ministry of Agriculture of April 11, 1939, "in view of the general economic situation, particularly the excessive fall in cotton prices" the period for cotton ginning is extended 15 days i. e. all the 1938 cotton crop must be ginned by May 15, 1939. The amount of cotton ginned up to March 31, 1939 is already larger than the second estimate of cotton production.

*Kenya:* Normal warm and dry weather prevailed throughout February. It was reported that the yield of cotton in Nyanza province would be considerably less than last season's.

*French Morocco:* Cotton sowing began in March in the Port-Lyautey area. Plants were growing at the end of the month.

*Nyasaland:* It was reported in February that issues of cotton seed had been smaller than in the previous season.

*Uganda:* During February weather conditions were hot and dry in the Eastern Province with the exception of a few heavy thunder showers in certain localities. In Buganda, Toro, Bunyoro and part of Lango rains were more evenly distributed than is usual during February. It was expected that yields in the drier areas would be smaller than anticipated. (See in the general table the revised crop estimate).

*Tanganyika:* It was reported in February that the Mwanza cotton crop had been estimated at 196,000 centals (41,000 bales of 478 lb.).

### Current information on Hemp.

*Hungary:* At the end of March the preparation of the land for hemp sowing was in progress.

*Italy:* Hemp sowings proceeded during the first half of March. Cold somewhat impeded operations during the second half of the month.

### Current information on Hops.

*Hungary:* At the beginning of April the pruning of hops had begun.

### Current information on Tobacco.

*Greece:* Tobacco production in Greece in 1938 amounted, according to official estimates, to 106,030,000 lb. against 151,471,000 lb. in 1937, a decrease of over 45,900,000 lb. This drop was due to the restriction by statute of the cultivation of tobacco, to the bad weather during transplantation and to poor rooting and low yields due to drought. These factors reduced the yield of tobacco so that though the area was only 12.8 per cent. lower, production was 30 per cent. lower. The decrease was not uniform in all departments. The largest decrease was in Thessaly where the area was 39.6 per cent. lower and production 60.2 per cent. less.

*Hungary:* At the beginning of April tobacco plants were sprouting in the seed-beds.

*Italy:* In the first half of March the growth of tobacco in nurseries was regular.

*Argentina:* Rain in February improved the condition of tobacco crops in Corrientes and the Chaco. In the other producing centres prospects are generally satisfactory.

*Canada:* The Canadian commercial tobacco crop reached record proportions in 1938. A preliminary estimate places production at 96,000,000 pounds from 83,000 acres as compared with 72,000,000 pounds from 69,000 acres in 1937. The increase was largely due to the expansion in flue-cured production, chiefly in Ontario.

CLASSIFICATION	Area thousand acres		% 1938 — 1937 = 100	Production thousand pounds		% 1938 — 1937 = 100
	1938	1937		1938	1937	
Bright flue-cured . . . . .	63,230	53,347	118.5	73,750	55,374	133.2
Burley . . . . .	9,215	6,142	150.0	10,650	6,371	167.2
Dark, air-cured or fire-cured . . . . .	3,000	2,197	136.6	3,200	2,000	160.0
Cigar type . . . . .	5,065	4,827	105.0	6,000	5,852	102.6
Large pipe . . . . .	1,980	1,396	141.8	2,420	1,710	141.5
Small pipe . . . . .	785	860	91.4	380	545	69.6
Miscellaneous . . . . .	—	231	—	—	241	—
TOTAL . . . . .	83,275	69,000	120.7	96,400	72,093	133.7

*Indochina:* There was drought in all parts in February. In Cochinchina picking was in progress. In Annam and Cambodia yields will be very poor, as crops have been seriously damaged.

*Nyasaland:* It was reported in February that, despite the continued heavy rainfall, the tobacco crop had made satisfactory progress. Normal yields were expected; it was anticipated that an increased quantity of good flue-cured tobacco would be reaped from the larger acreage planted this season, although the fire-cured crop would probably be smaller.

## Current information on Other Products.

### Cacao.

*Gold Coast and Togoland under British Mandate:* Main crop 1938-39. — The average rainfall and number of wet days in February were 3.02 inches and 6.5 wet days and were therefore slightly above the ten-year means of 2.57 inches and 5.2 wet days. Harvesting was completed. An increase in the percentage of mouldy, germinated, weevil and slaty beans was reported from up, country centres. Analyses of about 500 samples from farmers' stocks provided the following average percentages of defects: mould 2.7 per cent., germinated 4.2 per cent., slate 4.0 per cent., weevil 1.1 per cent., defective 1.2 per cent., The mean purity of the beans was 86.8 per cent.

The grade percentages are given in the following table.

*Grade per cent. during February 1939.*

	Farmers' Cacao (500 lots)	Original sampling (98,388,000 lb.)	Check sampling at ports (116,926,000 lb.)
I . . . . .	24.9	37.4	48.4
II . . . . .	39.0	55.7	49.1
III . . . . .	23.8	6.6	2.5
Sub-grade . . . . .	12.3	0.3	—
	100.0	100.0	100.0

The average number of beans in the standard 14 cubic inches space bean count for all ports during February was 126.1

Farmers' stocks were estimated at not more than 22.4 million lb. so that the fall in purity of cacao in farmers' hands is of small significance at that stage in the season and could have little effect upon the quality of cacao still to be exported.

All marketing continued at a steady rate although more slowly than in January. The total exports for the five months October to February amounted to 366 million lb., including 31 million lb. carry over; net exports of the new crop were therefore 335 million lb.

It was estimated that 90.0 million lb. of cacao were moved to the ports during the month by road and rail. Of this quantity 35.2 million lb. were received at Takoradi from Ashanti and the Western and Central Provinces, 41.4 million lb. entered Accra, and 13.4 million lb. were received at the Central Province ports.

The 1938-39 main crop was recently estimated at 582.4 million lb. by the Cacao Crop Estimate Committee. No decision was arrived at as to the exact stocks in mer-

chants' hands so that the usual estimates based on returns from exporting firms are not given, nor can the percentage estimates of the amount marketed, stocks in merchants' hands and in farmers' hands be computed. The aggregate estimate of the amount which is still to come in from all centres by the end of February was about 22.4 million lb.

MOVEMENT. — Movement statistics for February are as follows:

	February 1939	February 1938
	(million lb.)	
Railway off-loadings, Takoradi . . . . .	33.9	0.8
<i>Exports:</i>		
Takoradi . . . . .	43.6	2.8
Accra . . . . .	46.7	2.8
Other ports . . . . .	27.8	1.8
<i>All ports . . . . .</i>	<i>118.1</i>	<i>7.4</i>
Eastern Frontier . . . . .	4.0	0.0
<i>Total exports . . . . .</i>	<i>122.1</i>	<i>7.4</i>

## Tea.

*India:* In North India useful rain was received in most of the tea areas in February; no leaf was plucked. In South India dry weather continued and immediate prospects were considered to be only moderate; outturn was 10.12 per cent. ahead of that to the same date last year.

*Indochina:* The growth of tea plants was good in February in Annam.

*Japan:* The tea crop was in normal condition in April.

*Nyasaland:* It was reported in February that normal yields were expected from the tea crop.

## Coffee.

*Brazil:* The following table shows private stocks of coffee in regulated warehouses on December 31, 1938, left over from the three harvests 1936-37 to 1938-39, according to an estimate made by the Departamento Nacional do Café, with corresponding figures for December 31, 1937 and June 30, 1938.

	1938		1937
	31 XII	30 VI	31 XII
	ooo centals		
São Paulo . . . . .	12,774	5,642	9,275
In stations and trucks in São Paulo. .	—	1,371	2,749
Minas Geraes . . . . .	509	312	919
Espírito Santo . . . . .	61	34	395
Rio de Janeiro . . . . .	41	6	146
In stations, trucks and warehouses in Rio	263	150	725
Paraná . . . . .	25	87	68
	<hr/> 13,673	<hr/> 7,602	<hr/> 14,277

It should be noted that the large increase in the figure for São Paulo on December 31, 1938 is due to the fact that it also includes stocks in stations and trucks.

*Indochina:* The harvesting of the *Robustoïdes* variety of coffee was in progress in February in Tonkin.

*Angola:* The weather in February was favourable for coffee crops, the condition of which on March 1 was average.

*Madagascar:* The weather in February was rather dry and on the whole favourable for coffee plantations, the condition of which on March 1 was considered average.

*Tanganyika:* It was reported in February that prospects for this year's coffee crop from the Amsha and Moshi districts were favourable. The Bukoba coffee crop was estimated at 202,000 centals.

*Hawaii:* The condition of coffee crops on March 1 was considered good.

### Groundnuts.

*Bulgaria:* According to the latest estimate, the area cultivated to groundnuts in 1938 was about 6,300 acres against 7,000 in 1937 and 2,300 on the average of the five years ending 1936; percentages 89.8 and 271.0. The corresponding production is estimated at about 44,400 centals against 65,100 and 20,700 percentages 68.1 and 214.3.

*Argentina:* In March the lifting of groundnuts was in progress in Corrientes with good yields. The crop condition in the other producing centres was generally satisfactory.

*Burma:* According to the final estimate, the area cultivated to groundnuts this year is about 847,000 acres against 895,700 in 1937-38 and 642,300 on the average of the five years ending 1936-37; percentages 94.6 and 131.9. The corresponding production is estimated at about 4,032,000 centals against 4,581,000 and 3,257,000; percentages 88.0 and 123.8.

*Indochina:* In Cambodia and Cochinchina groundnuts were affected by drought; yields in March were mostly mediocre. Sowing was in progress in North and Central Annam. Sprouting was regular. In Binh-dinh and Phu-yên harvesting had begun. Yields were satisfactory on uplands and mediocre on low-lying fields.

*Netherlands Indies:* Java and Madura. — The Department of Agricultural Statistics of the Central Statistical Office communicates the following details of the groundnut area:—

	1939 acres	1938 acres
Area harvested in February . . . . .	46,700	40,000
Area harvested from January 1 to February 28 . . .	84,300	79,600
Area of standing crops at the end of February . .	130,700	147,500

## Colza and Sesame.

*Germany:* Crop condition of colza was 3.4 at the beginning of April, 1939 against 2.3 in December 1938 and 2.4 in April 1938. Corresponding figures for rape were 3.6, 2.6 and 2.4.

*Bulgaria:* According to the latest estimate, the area cultivated to colza in 1938 was about 53,700 acres against 8,600 in 1937 and 20,800 on the average of the five years ending 1936; percentages 626.5 and 258.2. The corresponding production is estimated at about 454,700 centals (909,400 bushels) against 61,500 (123,000) and 148,600 (297,200); percentages 739.4 and 306.0.

The area cultivated to sesame in 1938 was about 4,050 acres against 13,450 in 1937 and 12,430 on the average of the five years ending 1936; percentages 30.1 and 18.9. The corresponding production is estimated at about 5,100 centals (260 short tons) against 31,100 (1,550) and 62,400 (3,120); percentages 16.4 and 8.2.

*Hungary:* Winter colza crops on the whole passed the winter well. At the end of March growth was retarded owing to cold.

*Poland:* The severe frosts, without snow, of the second half of December did much damage to colza. Crop condition on March 15 was 2.9 against 3.6 on December 15 and 3.5 on March 15 of last year.

*Romania:* At the middle of April colza was growing in good conditions. Local damage by insect pests was reported.

*Yugoslavia:* According to the latest estimate, the area cultivated to colza in 1938 was about 43,900 acres against 39,500 in 1937 and 26,400 on the average of the five years ending 1936; percentages 111.1 and 166.1. The corresponding production is estimated at about 197,500 centals (395,000 bushels) against 181,700 (363,500) and 180,000 (360,000); percentages 108.7 and 109.7.

The area cultivated to sesame in 1938 was about 3,500 acres against 3,270 in 1937 and 1,840 on the average of the five years ending 1936; percentages 107.3 and 190.6. The corresponding production is estimated at about 10,500 centals (525 short tons) against 7,750 (390) and 3,650 (180); percentages 135.7 and 287.5.

*India:* Condition of rape and mustard was reported in mid-March to be fair.

According to the supplementary estimate, the area cultivated to sesame this year was about 4,261,000 acres against 4,450,000 in 1937-38 and 4,282,000 on the average of the five years ending 1936-37; percentages, 95.8 and 99.5. The corresponding production is estimated at about 8,848,000 centals (442,400 short tons) against 10,416,000 (520,800) and 9,677,000 (483,800); percentages, 84.9 and 91.4.

### Supplementary production figures.

As the 1938 or 1938-39 figure of production and area for most countries were published in the March number of the Monthly Crop Report and Agricultural Statistics, it is not necessary to repeat them again this month. Hence only new data and any modifications of the figures published last month are given in continuation. In another table is shown the total world production based on the figures received up to the time of going to press.

## Totals of world agricultural production.

The following totals have been obtained from the data in the tables published for each product in March, which have been revised and completed. With the name of each product is indicated the number of countries for which data for 1938 are at present available and also the percentage of the average world production in 1932 to 1936 as shown in the *International Yearbook of Agricultural Statistics 1938-39* (in the press) in which nearly all producing countries appear.

CROP (not including U. S. S. R. and China 1)	AREA					PRODUCTION							
	1938 — 1938-39	1937 — 1937-38	Average 1932 to 1936 — 1932-33 to 1936-37	% 1938 1938-39		1938 — 1938-39	1937 — 1937-38	Average 1932 to 1936 — 1932-33 to 1936-37	1938 — 1938-39	1937 — 1937-38	Average 1932 to 1936 — 1932-33 to 1936-37	% 1938 1938-39

### Current information on Fodder Crops.

*Germany:* Crop condition figures for the beginning of April 1939, October 1938 and April 1938 were respectively as follows: clover, 3.1, 2.7 and 2.6; alfalfa, 2.9, 2.6 and 2.5; irrigated meadows, 2.8, 2.5 and 2.6; other meadows, 3.0, 2.7 and 2.7; pasture, 3.0, 2.8 and 2.7.

*Bulgaria:* The latest estimates of production of the principal fodder crops in 1938, with comparative figures for 1937 and the average of 1932-36, are given below:—

		1938	1937	Average 1932-36	% 1938 1937 = 100	Average = 100
Vetches and black peas . . . . .	(ooo centals) * 10,275		5,132	(1) 3,339	—	—

\* Including seed. — (1) Average of 1934 and 1936.

*France:* The cold and wet weather of March was unfavourable for the growth of fodder crops but the first half of April was much more favourable and led to rapid growth. The outturn of rape, colza, vetches and red clover is expected to be mediocre. Growth at the end of March was sufficient to permit grazing in the south and on healthy, well exposed lands in general. The prospective shortage of hay and the poor production of green fodder will in any case induce farmers to pasture animals earlier than usual. In the mountains, however, indoor feeding had to be prolonged.

*Hungary:* At the beginning of April the planting of fodder beet had begun. In most areas alfalfa and clover had wintered well, but growth was retarded by cold weather. The growth of permanent meadows and pastures had begun but was retarded by the cold.

*Ireland:* The weather in March was cold and growth very backward. Pastures afforded less keep than usual, following the severe winter, but fodder supplies, though scarce, were anticipated to be sufficient for requirements.

*Italy:* The growth of meadows, pasture and annual fodder crops was delayed by cold. Unfavourable weather at the end of March impeded normal development.

*Latvia:* At the beginning of April only limited supplies of ordinary fodder of poor quality were available. Stocks of fodder roots were almost exhausted whereas those of potatoes were sufficient and of satisfactory quality. Only small quantities of concentrated feed were used for stock.

*Poland:* The winter was rather unfavourable for clover crops. Consequently, crop condition on March 15 was 2.9 against 3.2 on December 15 and 3.1 on March 15 of last year.

*United Kingdom:* The weather in March was variable. Cold north and east winds predominated with local snow or sleet. Rainfall was above normal in the east and in

Scotland. Pastures made little growth during the month. Winter keep was drawn on heavily and a shortage of hay was reported in some districts. An extensive use of concentrates was necessary to maintain milk yields.

*Switzerland:* Fields were snow-covered until the end of March and growth of grass is consequently late. Soil moisture, however, is sufficient and growth is likely to be vigorous with a rise in temperature. Despite the delay, grass looks well. Crop condition on April 1, 1939, in the system of the country, was 81 for temporary meadows (against 81 on April 1, 1938 and 84 on April 1, 1937) and 81 for permanent meadows (against 80 and 84).

*Argentina:* Rain in February considerably improved the condition of pastures in the country as a whole, except for parts of Buenos Aires Province and of Patagonia.

*Algeria:* Fodder cereals and rotation fodder crops had made good growth at the end of March. The growth of pastures, however, was slow, owing to the inclement weather of March. Spring growth was everywhere in evidence, seeds had germinated and it was estimated that if the temperature continued fairly high in April pastures would be normal.

*Egypt:* Growth of clover crops is satisfactory. Third cutting is progressing. Fourth cutting has been started in several localities. In Upper Egypt irrigated areas left for seeds are progressing towards maturity. Harvesting of early areas has been started. Crop condition is satisfactory.

*French Morocco:* Pastures in March were generally abundant, except in the mountains, and stock found plenty of feed, even in the south, which is rather rare.

## LIVESTOCK AND DERIVATIVES

### Pigs in Denmark.

## Livestock, meat production and meat markets in France in 1938.

*General livestock conditions and meat production.* — Feeding conditions were unfavourable in 1938 and, for cattle, the year was also marked by a severe outbreak of foot-and-mouth disease. Fodder production in 1937 had been rather good and winter conditions were favourable but the following spring and summer brought unfavourable conditions which did not improve appreciably until the autumn. The fodder production of 1938 was consequently mediocre. Foot-and-mouth disease had serious effects on herd numbers and births and on the conditions and employment of animals.

The official statistics of meat consumption have not yet been published but the figures compiled by the *Association générale des Producteurs de Viande* indicate the changes that have occurred, at least as far as State controlled and taxed slaughterings are concerned. These figures do not cover meat obtained from farm slaughterings and consumed on farms, this proportion being substantial in the case of pigs (1).

*Index Numbers of Quantities of Meat subject to Slaughter Tax.*(calculated from the figures of the *Association générale des Producteurs de Viande*)

Years	1927 = 100					
	Beef	Veal	Pigmeat	Horse-meat	Mutton and Goat meat	Total
1938 . . . . .	115	117	162	100	101	124
1937 . . . . .	114	117	166	112	95	124
1936 . . . . .	119	125	164	115	89	127
1935 . . . . .	116	126	167	118	87	126
1932 . . . . .	97	109	149	122	97	112
1931 . . . . .	94	99	152	128	87	108
1929 . . . . .	116	108	121	128	99	114
1927 . . . . .	100	100	100	100	100	100

Slaughterings of adult cattle increased slightly on 1937 but those of young animals showed no change while horses decreased considerably. The main features were a large increase in sheep slaughterings and a decrease in pig

(1) See note on the following page.

slaughterings unless there was an increase in the farm slaughterings of pigs, an unlikely development since the prices of live animals were high (1).

The changes noted in slaughterings should correspond at least roughly with the change in the number of livestock. Net additions to and withdrawals from animal numbers in 1938 were appreciable for all species.

*Net Imports (+) or Net Exports (—) of Live Animals.*

	1938	1937	1936	1935	1934	1933
	(Thousand head)					
Cattle . . . . .	— 2.9	+ 4.9	+ 9.0	— 6.3	+ 1.9	+ 24.7
Sheep . . . . .	+ 800.1	+ 870.6	+ 1,053.2	+ 868.3	+ 785.0	+ 790.9
Pigs . . . . .	+ 10.0	+ 13.1	+ 35.4	+ 27.0	+ 77.5	+ 172.7
Horses for meat. +	9.9	+ 47.3	+ 18.0	+ 6.2	+ 7.3	+ 15.2

The changes are mainly due to a decrease in animal imports from Algeria and Tunisia where feeding conditions were poor and losses from foot-and-mouth disease serious. There was however, some recovery in exports, especially cattle.

A rough calculation based on average coefficients shows the following changes since 1937 in the slaughterings of domestic animals:—

Increases: 25,000 to 30,000 cattle, mainly adult animals; 250,000 to 300,000 sheep; 15,000 to 20,000 horses;

Decrease: about 100,000 pigs.

Apart from their direct effects on market supplies and the numbers of animals, imports and exports merit attention for their own interest. Trade in meat and animal derivatives must be considered as well as that in live animals.

*Net Imports (+) or Net Exports (—) of Dead Meat,  
in various forms, and Animal Fats.*

	1938	1937	1936	1935	1933
	(000 lb.),				
<i>Fresh and frozen meat:</i>					
Imports:					
Mutton . . .	(+ 17,879)	(+ 23,589)	(+ 18,078)	(+ 17,571)	(+ 19,886)

Beef and other meats , . .	(+ 27,624)	(+ 29,939)	(+ 21,627)	(+ 25,508)	(+ 47,311)
Total . . . .	+ 45,966	+ 56,879	+ 43,387	+ 45,945	+ 84,966

(1) The official figures, published when the *Crop Report* was in the press, show variations very similar to those indicated above for all Kinds of meats, except for pigmeat. The quantity of pigmeat from commercial slaughterings was the same in 1938 and in 1937, but the slaughterings for home consumption on farms show a diminution and the percentage diminution for total pigmeat production between 1937 and 1938, as indicated by the official figures, is equal that indicated by the unofficial and incomplete figures above, i. e. — 2.6 per cent.

Like imports from foreign countries, which are subject to strict quotas, and from North Africa, exports of live cattle, meat, fats and lard declined. The drop in domestic prices of cattle and the fall in the exchange seem to have been the real causes of the recovery.

The official returns are not a census taken at a fixed date but estimates made at the beginning of the winter. No indication of the date is given but it appears that in the last two years the returns have been made on November 1, not on December 31. The figures for 1938 and 1937 would thus be comparable between themselves but not strictly comparable with those of earlier years. On the other hand, an anomaly appears in the figures for mules for 1938. The increase in mule numbers cannot be accounted for by any visible, supplementary imports and it occurred practically entirely in one *département*, that of Gironde where the numbers increased from 3,660 to 30,700 between the end of 1937 and the end of 1938. Furthermore, as a result of the enquiry into milk production, the number of cows at the end of 1937 was 50,000 greater than the figure in the annual estimate. This increase has affected the total number of cattle and it must be kept in mind when comparisons are made with previous years.

If these reserves and corrections are made, it is possible to observe appreciable changes in the livestock situation.

The decrease in *horses and asses* is one of the most marked that have occurred since the war. It was 1.8 per cent. for horses compared with an average of 1.0 per cent. in years prior to 1937, the previous largest being 1.4 in 1936. For asses it was 5.3 per cent. compared with an average of 2.0 per cent. and a maximum of 5.4 per cent. in 1932. The decrease was partly due to slaughtering for meat (15,000 to 20,000 more than in 1937 of a total decrease of 60,000 head). On the other hand, the fall in the number of colts and fillies was relatively light (1.4 per cent. only) though there were marked decreases in the years 1929 to 1934. The decline in numbers, at least in the case of horses, thus seems to be due mainly to the earlier downward trend. The latter was marked by smaller output of live animals and by considerable slaughtering for meat, and it is apparently reflected in a decline in the numbers of young mares. Hence a persistent decline in the natural growth in horse numbers.

(1) Comprising 4,156,000 cows kept exclusively for milk and 3,856,000 kept for milk and other purposes, a total of 8,012,000 milk cows representing 90 per cent. of the total number of cows.

*Cattle* suffered especially from poor feeding conditions and foot and-mouth disease. The latter resulted directly in higher mortality and in a reduction in calvings and indirectly in more slaughterings of cows and heifers and fewer steer slaughterings.

The total number of adult cattle declined and, still more remarkable, the number of cows decreased considerably but the number of steers and oxen increased slightly. This dual development is the reverse of previous experiences.

*Index Numbers of Numbers of Adult Cattle.*

(\*) Calculated with an allowance for the correction made in 1937 in the numbers of cows.

Total adult cattle numbers fell by 96,000 head. The increase in cattle sold for meat or export was 25,000 to 30,000 head. The difference between the two figures is due partly to foot-and-mouth disease and partly to the fact that fewer young animals, especially heifers, which reached their third year in 1937, were kept for breeding. The more marked effects of foot-and-mouth disease on cows and heifers, smaller production and reduced working capacity undoubtedly resulted in greater slaughterings for meat while steers and bulls, young and adult were preserved.

The larger percentage of the slaughterings of cattle of one year old and over at the end of 1937 is shown by the fall in the proportion of this category to that of young calves born in the two previous years and not slaughtered in the year of their birth; this proportion, which was increasing fairly considerably, declined in 1937 and 1938. In contrast to previous years therefore, it seems that in 1938 a larger number of animals born during the two preceding years were killed and less calves born during the year. The decrease in the number of young cattle under one year old is thus due simply to a decline in the number of births and this decline seems to have been larger than would appear from the decrease in the number of this category. The same phenomenon was noticeable in 1937, while in previous years the decrease in the number of calves, born during the year and not slaughtered in the same year, per 100 cows existing in the preceding winter resulted from the play of two opposing factors, namely, a steady increase in the number of births, due to the increase in the number of cows, and an increasing proportion of slaughter of calves.

Finally, it should be noted that, mainly owing to the epidemic of foot-and-mouth disease, the natural increase in the number of cattle was less than the slightly increased demand in 1938 on the meat market. The resultant double decrease in the number of young cattle and of full-grown cows took place for the first time for many years.

*Percentage Comparisons of Young Cattle at the end of the year.*

	Proportion of young cattle one year old and over not slaugh- tered during year to calves under one year old at end of the two prece- ding years.	Proportion of young cattle of one year old and over, not slaughtered du- ring year, to number of cows at end of pre- ceding year.

\*\*) Calculated with an allowance for the correction made in 1937 in the numbers of cows.

The same situation is found with a more general character, but for different reasons, in the case of *sheep and goats*. The decrease of 153,000 in the aggregate number of sheep and goats does not correspond at all to the much larger increase of 250,000 to 300,000 in slaughterings. Thus, the natural increase in the numbers of sheep and goats, resulting from the recovery in these categories in the two previous years, was insufficient to satisfy a heavily increased demand due to the development of mutton consumption and to the lower imports of sheep from North Africa. Among sheep the largest decrease was in the number of full-grown sheep for fattening (7.1 per cent.), while their numbers had risen 2.5 per cent. between 1935 and 1937, but the number of lambs under one year old, not slaughtered, per 100 ewes at the beginning of the winter has fallen to 40.3 against 41.7 in 1937 and 41.4 in 1936; the net increase in numbers was thus small.

The total number of lambs under one year old decreased (— 1.9 per cent. against an increase of 6.6 per cent. between 1935 and 1937) and there was also a decrease in the number of full-grown ewes (— 1.1 per cent., against an increase of 4.9 per cent. between 1935 and 1937).

The situation is exactly the reverse in the case of *pigs*. There was a slight increase in the total number, but this rise of 10,000 does not at all correspond to the fall in slaughterings (100,000). Except in the unlikely case of a large development of slaughterings and of direct consumption on the farm, there was thus over-production of pig-meat, in spite of a falling off in the natural increase of pigs. This is reflected in the fairly considerable decrease in the number of full-grown sows (1.3 per cent. compared with 1937 and 2.5 per cent. compared with 1936), while the over-production of meat is shown particularly in a slight increase in the number of animals under six months old for fattening (0.6 per cent.) in face of a decline in consumption. The comparatively high number of young pigs, not slaughtered, per 100 sows, during the preceding winter is an even clearer index of over-production (40.9 per cent. against 40.2 in 1937, 40.7 in 1936 and 39.8 in 1935).

*The meat market and prices during the 1938-39 season.* — The meat market was fairly irregular during 1938.

While in 1937 the general tendency to rise had practically offset the seasonal decrease during the summer, in 1938 there was a sudden, very sharp drop in cattle prices at the end of the spring, this market being affected by the general conditions of stock breeding. The drop was at first heavier in the case of unfattened cattle (— 26.3 per cent. between April and June) and for calves (— 24.6 and — 28.3 per cent. according to quality). Subsequently, the prices of calves increased and nearly returned to the level of January 1938. The prices of full-grown unfattened cattle (second quality) also rose considerably, but later fell to the lowest level of the previous summer and the quotations for extra-quality fat cattle remained very low. The average price of 1938, however, for all categories remained higher than in 1937, but the increase is very small compared with the fall in the purchasing power of money due to currency devaluation.

On the other hand, the prices of sheep and pigs increased, the rise was higher for unfattened sheep than for fat sheep, owing to the lower imports from Algeria

of the former category. On the aggregate, the increase corresponds approximately to the depreciation in the purchasing power of money. Quotations for pigs alone showed at the end of the year a real and heavy increase, but this was almost completely eliminated by the fall in prices, resulting from declining consumption, during the first quarter of 1939.

Prices of the *cinquième quartier* (hides and skins) were fairly well maintained on the whole, and following the fall in the spring there was an appreciable rise up till November.

*Value of the cinquième quartier (hides and skins)  
per kilo of net weight of meat on the carcass.*

In addition, it should be noted that, although the prices of certain feeding stuffs for livestock—cereals and milling offals—have declined, those of straw, fodder and cakes have increased in some cases to a very large extent. The rise was at least proportional in the aggregate to the rise in prices of live weight of meat.

*The general livestock situation at the beginning of 1939.* — Except for horses and goats, for which detailed statistics are not available, a decrease may be forecast in the other three categories—cattle, sheep and pigs, owing to the fall in the number of full-grown females and young animals. This is particularly noticeable in the case of cattle, for which the ravages of foot-and-mouth-disease, the poor feeding conditions and the severe cold of the winter must also be taken into account. Moreover, the demand for meat on the market has remained fairly restricted on the whole during the first quarter of the year, particularly in the case of full-grown cattle and pigs.

The cattle breeding situation at the beginning of 1939 seemed rather unsatisfactory and that of pig breeding was also depressed, following the remarkable developments of the last few years. Sheep breeding seems to be in a better position but the maintenance of this improvement depends partly on the trend of the consumption of mutton and partly on the size of imports from North Africa.

**Livestock in Canada.**

The following table shows the number of livestock on farms in Canada on December 1, 1938, compared with the corresponding figures for December 1, 1937

	Cattle	Sheep	Pigs under 6 months	Pigs over 6 months	Hen and chickens
December 1, 1938 . . . . .	8,091,100	2,671,600	2,340,500	1,228,100	40,752,700
December 1, 1937 . . . . .	8,079,900	2,673,800	2,296,000	1,384,400	39,564,000

The numbers of cattle on December 1, 1938 were 0.1 per cent. above those at December, 1 1937. This slight increase indicates that the cycle in cattle numbers has turned upwards and this trend is expected to continue for the next few years. A further indication of the upward trend is the increase of 1.1 per cent. in the numbers of cows expected to calve this spring.

Sheep numbers were 0.1 per cent. less than at December 1, 1937 and there is a decline of 3.6 per cent. in the number of ewes expected to lamb this spring.

The number of pigs was lower by 3.0 per cent. Pig numbers have been declining since 1936 but an increase in December over June, 1938, indicates a reversal of this trend. Better feed prospects will result in an increase in production. A rise of 14.9 per cent. was reported in the number of sows expected to farrow this spring compared with last spring.

The number of hens and chickens on farms on December 1, 1938 was 3.0 per cent. over the figure for December 1, 1937.

### **The Early Spring Lamb Crop in the United-States.**

An early spring lamb crop slightly smaller than the early large crop of last year is indicated by reports received by the Bureau of Agricultural Economics. The numbers of early lambs for slaughter before July 1, however, will be materially smaller than last year because of the very poor condition of the lambs in California and Texas where a large proportion of the early crop will not reach slaughter weights and condition by that date.

Weather and feed conditions in a number of the important early lambing States have been much less favourable up to March 1 than last year, and prospects for feed in some of these States during the next two months are not promising. Growing conditions last year were generally favourable throughout the season in all of the early lambing States.

In California, the most important source of early lambs, the present and prospective feed situation is very poor in most of the early lambing areas, and it now seems fairly certain that a large proportion of the early lambs will have to be sold as feeders. In Texas, which last year ranked second in the number of early lambs marketed before July 1, weather and feed conditions have been very unfavourable since the first of the year. Losses of early lambs have been heavy and most of the lambs have not made normal growth.

Conditions have been much more favourable in the other early lambing States. In the North Pacific States and Idaho, weather has been fairly favourable for shed lambing and feed supplies have been abundant and cheap. In the South-eastern states the proportion of ewes lambed to March 1 was below last year and hardly up to average, and in Tennessee and Kentucky the shortage of winter grain pasture has handicapped somewhat the growth of the lambs.

The situation as of early March indicated that the slaughter of sheep and lambs during the 3 months from April through June this year will be considerably smaller than the large slaughter during these months last year. Not only will the number of early spring lambs be smaller but the movement of grass fat yearling lambs and wethers from Texas will also be much smaller.

### Mohair Production in the United-States.

Mohair production in the United-States in 1938 is estimated to have reached about 16,762,000 lb. against 16,368,000 lb. in 1937. The numbers of goats and kids clipped were 3,876,000 and 3,722,000 respectively. The average clip per goat was 4.3 lb. in 1938 compared with 4.4 lb. in 1937.

### Butter Production, Trade and Prices in 1938.

The weather conditions of 1938 were fair to good for dairy production. In Europe, the spring, though mild at first, was cold and very dry on the whole. Pastures and fodder crops were consequently late and milk production was less plentiful. The hay harvest was not satisfactory in all parts but the shortage was generally made up by good second cuts. During the second half of the year, conditions for milk production in Europe were generally favourable. Foot-and-mouth disease abated and its effects on milk production were less noticeable.

Conditions in North America were particularly favourable for milk production, fodder production being favoured by adequate moisture, especially in the United States.

The year was favourable for milk production in Australia and, at least during the summer, in Argentina, but in New Zealand conditions were unfavourable on the whole.

Butter production was consequently adequate on the whole and in some places very plentiful.

The statistics of butter production given in the accompanying table in most cases do not relate to total production. The figures are generally those for creamery production but even such figures are not quite comparable owing to differences in the compilation of returns. Although this table appears for the first time, no explanation of the differences in the material can be given. The notes accompanying the table are sufficient to give a general outline. Speaking generally, statistics of creamery production are more accurate than those of farm production though there are cases in which returns on farm butter for certain countries are more exact than the creamery returns of certain other countries. Data for 1938 are incomplete and partly provisional.

The main producer is the United States. Production in this country has shown relatively slight variations during the years considered though the difference between 1937 and the record year 1936 is greater than the total production of Belgium or Sweden. Germany, the other large producer, has recorded a substantial rise in production representing a quarter of its 1931 production. There has occurred not only a general increase in production but also a shift in the relative importance of production sources. On the one hand, creamery production has doubled and, on the other, farm production has been halved in five years. This has undoubtedly resulted in an improvement in quality. Production in Germany in 1938, however, did not reach the 1937 level.

At a fair distance behind the two countries mentioned there follows a group of medium producers, the chief which, in order of importance are, according to the latest figures, France, Australia, Denmark, New Zealand, Canada and the Netherlands. The order would probably be different if the returns of all countries were compiled on the same basis.

One aspect not revealed in the table is the composition of the milk production used for butter-making in Greece. Of the total 1937 butter production of 13,300,000 lb., 2,600,000 lb. was made from cows' milk, 1,300,000 lb. from buffaloes' milk, 4,000,000 lb. from ewes' milk and 5,300,000 lb. from goats' milk. The relative importance of the different kinds has changed only slightly in recent years.

Half the quantities indicated for Bulgaria represent whey butter.

For 1938 Lithuania, in addition to figures for the production of co-operative creameries given above, has compiled figures for private creameries for the first time. Production from these was 431,900 lb. making a total of about 43,300,000 lb.

The aggregate production figure given for of the countries included in the table was about 6,400 million lb. in 1937, 6,220 million lb. in 1936, and 5,560 million lb. in 1931. As we have indicated above, these figures do not represent the total production of the countries enumerated.

The butter exports of Denmark, New Zealand and Australia, the three principal exporting countries, show substantial changes in relative importance from

those of the previous year. In the first place, there has been an increase in the gap between the exports of Denmark and those of New Zealand after the latter had wiped out the difference which existed in 1930 between the exports of the two countries, an expansion in the one country coinciding with a contraction in the other. New Zealand's exports in 1937 are the highest hitherto recorded. Denmark, on the other hand, succeeded in increasing her exports at the same rate as in other years following the 1935 minimum and consolidating her position on both the British and German markets. The largest increase over the previous year occurred in Australia whose exports have fluctuated widely in the period under review usually from one year to another. In earlier years the exports of this country, at about 8,800,000 lb., were only half those of the years indicated in the table. Increases being the rule in other exporting countries, it is likely that total exports in 1938 were more than 4,400,000 lb. larger than those of 1937.

There has been a corresponding increase in the principal importing countries, namely, the United Kingdom and Germany. The increase over 1937 is about the same in both countries but is proportionately larger in Germany. Canada's imports were exceptionally large although butter production was larger than in previous years. In the United States, on the other hand, increased domestic production was accompanied by lower imports.

(1) Re-exports have been deducted. — (2) From the International Yearbook of Agricultural Statistics.

The imports of the United Kingdom are given in a separate table showing their countries of origin. The preceding table gives retained imports but this special table shows gross imports less re-exports and exports of home-produced

butter and the resultant net imports. The figures of retained imports given in the general table are not repeated in the special table.

*Imports of Butter into the United Kingdom by countries of origin.*

The United Kingdom's main supplier, New Zealand, recorded a reduction almost equal to the total reduction in her exports, the United Kingdom being practically her only market. With the exception of the U. S. S. R., whose exports to Great Britain, like those to Germany since 1937, have ceased completely, other important suppliers succeeded in exporting the same quantities as in 1937 and in many cases even larger quantities. Denmark has almost caught up with New Zealand on the British Market. The price of Danish butter did not increase to the same extent as that of other butters. The price advantage enjoyed by Danish butter in 1934 has been considerably reduced also as compared with the previous year. Consequently, the other suppliers were able to secure a relatively better return by the increase in their sales on the British market. One development worthy of note is the rapid growth in Latvia's exports.

*Import of Butter into Germany by countries of origin.*

(Thousand lb.).

COUNTRIES OF ORIGIN	1938	1937	1936	1935	1934	1933	1932	1931
Denmark . . . . .	80,537	75,559	73,502	56,291	42,933	36,678	29,196	67,541

(1) Hamburg: Schleswig-Holstein.

\* Not quoted during part of the period.

International comparisons of butter prices, which are expressed here in gold francs, must be made with reserve in view of the differences in real price levels from country to country. The quotations without exception show increases over the previous year and a continuation of the rise which began in 1934. In fact, the rise became more general and was extended to Germany. With the exception of this country, however, prices are still considerably below the levels which ruled before the serious decline, as is shown by the quotations for 1931. The series also shows that the differences between various prices have increased from 1931 to 1934. During the decline, these differences were apparent not only as between one country and another but also in quotations for butters of various provenance on the London market. Particularly noteworthy is the privileged position held by Danish butter. Subsequently, those prices, which were exceptionally low in 1934, showed a marked rise, whereas prices of other butters did not increase to the same extent. Thus, the gap between the various quotations is once again diminishing.

Monthly prices are mainly a reflection of seasonal fluctuations in production. London prices for Australian and New Zealand butters are highest in the second quarter of the year.

W. SCHUBRING.

### Current information on Livestock and Derivatives.

*France:* Foot-and-mouth disease is abating noticeably and seems to be disappearing completely but farmers, especially those in the *départements* affected by frost, are experiencing great difficulties in maintaining their animals in good condition owing to acute feeding problems. In many cases they have been obliged to dispose of part of their stock earlier than usual.

*Ireland:* Milk production was adversely affected in March by the severe weather and somewhat limited supplies of fodder and roots, but nevertheless was up to the level of the corresponding period of 1938.

*Latvia:* Milk production increased 5 to 10 per cent. over the previous month. The principal cause of this increase was the rise in the number of milch cows.

*Argentina:* The condition of livestock in March was good throughout the country. The second wool clip in Patagonia was poor.

*United States:* Milk production per cow in the United States on March 1 was well above that of a year earlier and nearly 5 per cent. above the ten-year average for March 1. Although production per cow showed somewhat less than the usual seasonal rise during February, abundant feed supplies on farms and liberal feeding of grain and concentrates to milk cows apparently offset much of the unfavourable effects of subnormal temperature and heavy snows over a large portion of the country late in February.

Pastures seem to have begun the year in normal condition. Condition on April 1 was 79 per cent. of normal, the second highest for that date since 1930 but lower than on any April 1 in the 1924-29 period, prior to recent droughts. Reports from the Southern States showed pastures furnishing less feed than a year ago but condition was rather generally above the low 1928-37 average except in California, Texas and Florida. Reports from the Northern States indicated prospects for pastures mostly about average or better, but in Kansas, Nebraska and the Dakotas the condition was still markedly lower than before recent drought years.

Milk production on April 1, after a much sharper than usual seasonal increase during March, was the highest on record for that date from the standpoint of total milk production, production per cow and production per unit of population. Abundant supplies of hay and grain encouraged farmers to feed their milk cows liberally in the late months of the winter feeding period, and in the southern half of the country, pastures, although later than a year ago, are furnishing some feed for milk cows.

*Algeria:* The abnormal cold and excessive rain of March checked the improvement in the condition of livestock. In Alger and Oran sheep remained thin owing to the retardation of growth and the flooding of many pastures by rain. In Costantine the situation, however, was satisfactory both in the littoral and the sub-littoral (Tell.). There was also a tendency to improvement in the tablelands and the south.

*Union of South Africa:* Very heavy rains fell in the summer rainfall areas of the Union in February, and good rains also fell even in most parts of the winter rainfall areas. Consequently, grazing improved very considerably throughout the Union, and prospects for livestock during the winter were very favourable. Sheep were adversely affected in some parts of the east by excessive rain and flooding.

**Current information on Sericulture.**

*Indochina:* In Annam, the second sprouting of mulberries began vigorously in February and enabled the minor rearings to be begun. The condition of worms was poor owing to changes in temperature during the month.

<sup>(1)</sup> Average rates for entire cargoes, except where otherwise stated, relating to contracts made, during periods often extending back several months, to operate during the weeks specified. For more detailed explanations see the article with the same title on p. 392 of this Crop Report. — <sup>(2)</sup> Shipments of wheat and maize: Aug.-July. — <sup>(3)</sup> Rates for parcels by liners. — <sup>(4)</sup> Before October 1937, rates for parcels by liners. — <sup>(5)</sup> Freight rates quoted at Braila, not comparable with the other rates.

## OCEAN FREIGHT RATES

Freights are an important element of cost and account for the greater part of the difference between the c. i. f. price on the import market and the price on the export market. It is for this reason that information on freight rates is given in the Crop Report.

At the moment of purchase of a parcel or cargo of grain on an import market, at a c. i. f. price to be shipped during the current month, or afloat, the shipping conditions are generally settled, so that the shipper can allow in his order, for the charges actually borne by the goods. The same is true of a c. i. f. sale of grain already in port. The prices given in this Crop Report relate wherever possible to goods that have arrived (spot) or are about to arrive. Hence, for comparisons between different markets, the freight actually paid, not the freight ruling at the time of shipping, which may not be for some months, is of first importance. Therefore, freights indicated in these tables represent, as far as possible, the average rates for contracts entered into during a period often going back several months to be applied during the period indicated.

The specifications hitherto given in the tables have been rather vague. This was especially the case for "United Kingdom" and "United Kingdom Continent" ports. A shipping contract does not stipulate a single freight rate for the transport of cereals to any United Kingdom or Continental port but, in addition to the basic freight rate for certain ports where it is possible to unload rapidly and usually to take on other cargoes (these are known as "picked ports"), supplementary charges are made for unloading at other ports.

Some examples of variations in basic freight rates are given below. Shipowners now make agreements on the minimum freight rates to be paid by cereal merchants. One of these agreements relates to shipments from Atlantic ports of the United States south of Cape Hatteras and from Gulf ports to European destinations. Minimum freights from Gulf ports were 3/6 per quarter (480 lb.) of wheat or maize from September 15, 1938 to March 23, 1939 for picked ports United Kingdom/Continent (abbreviated to p. p. U. K./C.) and from that date 3/3. These ports are London, Hull, Cardiff, Barry, Swansea, Antwerp, Rotterdam or Amsterdam. For barley, the minimum rate is reduced by 2d. per quarter of 400 lb., for oats by 4d. per quarter of 320 lb. For other ports supplements must be paid, e. g., 1d. for Leith, Avonmouth or Dunston; 2d. for Manchester, Liverpool, Birkenhead or Glasgow; 3d. for other British ports and certain Irish ports; the same for Continental ports between Antwerp and Hamburg (including the latter) other than Antwerp, Rotterdam, Amsterdam and the Weser ports; 4d. for certain difficult Irish ports (slow Irish ports) and for Weser ports; 6d to 9d. for French, Spanish, Italian or Portuguese ports.

There are also other agreements (Schemes of Co-operation) which fix minimum freights for grain shipments to Europe. These cover shipments from ports on the St. Lawrence and the North Atlantic Coast ("Northern Range", including Albany), from River Plate ports and from Australian ports.

From St. Lawrence ports, Halifax, St. John (N. B.) and United States ports up to Albany, the minimum basic freight rate is 2/9 for the picked ports mentioned above with supplements about equal to those of the agreement relating to Gulf shipments.

Plata ports are divided into two principal groups, namely, Down River und Up River. Base freights apply to Up River ports not above San Lorenzo. For shipments of cereals to British picked ports (in this case, London, Hull, Cardiff, Barry,

Avonmouth, Liverpool or Birkenhead) the basic freight is 20/- per long ton (for shipments prior to March 18, 1939 the minimum was 25/-, other conditions being the same). An increase in freights of 1/3 is made for Colastine, Santa Fé, Concepcion and Paraná, and a reduction for Down River ports (od. Mar del Plata, 1/- Buenos Aires or La Plata, 1/3 Montevideo or Bahia Blanca). For unloading at Antwerp or Rotterdam, reductions of 6d. and 3d. respectively are allowed. For Amsterdam the rate is the same as for British picked ports. There are a number of increases, the chief being 3d. for other British ports and northwestern Continental ports; 1/- for German ports; 1/3 for Marseilles, Genoa, Naples, or Leghorn; 1/9 for Italian ports other than those mentioned or those on the Adriatic, and 2/6 for Adriatic or Greek ports.

Shipments from Australia to Europe have a minimum rate of 31/- per long ton of cereals shipped in bulk from South Australia or Victoria to a United Kingdom port, other than a slow Irish port, or to a northwestern Continental port. From a Western Australia port the minimum is 30/-; from Sydney or Newcastle (New South Wales) it is 30/6 for loading ex-silo and 31/- ex-sacks. All these rates are increased by 2/6 for loading in sacks. Increases of 1/3 are applied for unloading at Marseilles, Genoa, Naples or Leghorn, 2/9 for Adriatic ports, 3/- for Port Said or Alexandria. The agreement also fixes minimum rates for shipments to Far Eastern ports with Shanghai as base. These are 17/- for bulk shipments from South Australia or Victoria, 16/- from Western Australia, 15/- from Sydney or Newcastle ex-silo and 15/6 ex-sacks; sack shipments 1/6 more. Prior to March 25, 1939 minimum rates for Europe were 1/- higher.

All agreements also provide for increases in case of loading or unloading at more than one port and for reductions on vessels carrying more than a fixed minimum cargo of grain (8,000 long tons for La Plata, 8,250 long tons for Australia and 15,000 quarters for North America).

This summary shows that the calculation of the average actual freight over a given period for the transport of a given quantity of maize or wheat is extremely complicated. We therefore indicate only the average freight which would probably be paid for shipments from a base port to London or to a port for which the rate is usually equal to that for London. The table of freights has been revised as far as possible in accordance with this criterium.

(1) The gold franc adopted is that of the former Latin Monetary Union. Original prices have been converted into American dollars, and multiplied by 3.061, which is the coefficient existing between the current dollar and the former franc of the Latin Monetary Union. In cases where the difference between the rates of exchange of the national currency considered, and parity with the dollar did not, during a given month, reach 2½%, the monthly average has been converted on the basis of parity. In other cases the average rate of exchange for the month has been utilized. — (2) Before August 1937: "Barusso". — (3) Calculated on the basis of the relation between the korona and the Reichsmark.

## VARIATIONS IN THE INDEX-NUMBERS OF PRICES

The index-numbers of prices of agricultural and other products of interest to the farmer, as published by the various countries, are often very heterogeneous and consequently great care has to be taken in drawing conclusions from the supplementary information given in the following comparative summary table.

COUNTRIES	Percentage variations in the index-numbers of prices of			
	agricultural products	all products	agricultural products	all products
	March 1939 in comparison with			
	February 1939		March 1938	
Germany (products sold by farmers) . . . .		—	+	2.0
Germany (wholesale prices) . . . . .	+	0.2	+	2.1
England and Wales (a) . . . . .	—	3.2	—	1.1
England and Wales (b) . . . . .	+	2.3	—	1.7
Argentina . . . . .	+	5.4	+	20.4
Australia . . . . .	+	3.8	+	0.5
Canada . . . . .	+	0.6	—	21.6
United states: Bureau of Labour . . . . .	—	2.1	—	6.4
Finland . . . . .	—	3.4	—	0.0
New Zealand . . . . .	—	1.0	—	1.3
Netherlands . . . . .	+	5.0	—	1.6
Poland . . . . .	+	0.4	—	4.8
Sweden . . . . .	—	0.7	+	3.8
Switzerland . . . . .	—	0.0	+	4.1
Yugoslavia } vegetable products . . . . .	—	0.6	+	1.1
} animal products . . . . .	+	1.9	—	3.8

(a) Not corrected for seasonal variation. — (b) Corrected for seasonal variation.

## VEGETAL PRODUCTION

*Belgium:* Except in the first and last days of the month, March was unfavourable for agriculture. It was cold and wet and there were falls of snow and hail. *Wheat* resown early sprated fairly well and in many cases had a better appearance than crops which had survived the December frosts. A large expansion in area under *oats* and *flax* is forecast. The appearance of *clover* and *alfalfa* is unsatisfactory owing to the severe frosts. *Meadows* are mediocre.

### The World Wheat Trade in 1938-39 and 1939 Wheat Crop Prospects.

#### The World Wheat Trade in 1938-39.

Wheat trade in March, the last month for which official statistics have been received by the Institute for the principal exporting and importing countries, was maintained as in January and February, at about the same level as last year, when trade was very restricted owing to the small exports of Argentina following her poor 1937-38 crop. This year this great exporting country has had a very large crop, as is confirmed by the final estimate recently published (336 million bushels against 185 millions last year and an average of 232 millions in the five preceding years). But in spite of the large surplus provided by her new crop Argentina has not disposed of large quantities on the international market. Exports from January to March 1929, were only 30 million bushels, or little more than the 20 millions exported in the same period of 1938. Two years ago with a much smaller surplus than this year's, Argentina had already in the quarter January-March 1937 disposed of 93 million bushels, or more than three times the amount disposed of in the first quarter this year. Exports from Australia, on the other hand, in spite of the rather small size of her new crop, continue at nearly the same level as last year, owing to a recovery in demand on the Far Eastern markets and the return of India to importing.

The exports of the United States also approach the level of last year, while the exports of Canada, alone of the four principal exporting countries, show a considerable increase. The total world exports of the first eight months of the

\* Aggregate net exports of the normal exporting countries (possible net imports into certain of these countries are not deducted from the totals).

(1) Forecast March 1939. — (2) Net exports adjusted in accordance with the monthly variations in stocks of Canadian wheat in the United States and stocks of United States wheat in Canada. — (3) Bulgaria, Lithuania, Poland and Yugoslavia. — (4) Iran, Iraq, Turkey, Chile and Uruguay. — (5) Net imports.

season have been divided roughly as follows. Canada has supplied about 30 per cent., the United States, Argentina, Australia and the group of Danube countries about 15 per cent. each and the U. S. S. R., North Africa and the group of minor exporting countries about 10 per cent. on the aggregate.

From August through March, or during two thirds of the season, the net exports of wheat totalled 394 million bushels, or only 33 millions more than last season, when they were at one of the lowest levels of recent years. In March we had estimated that the probable world import demand for the whole of the season would amount to 570 million bushels. From the trade figures of the first eight months of the season it does not appear necessary, at any rate at present, to revise this forecast. It requires, in fact, total exports from April 1 to July 31 of 176 million bushels, at an average of 44 millions per month, against an average of 49 millions actually exported in the preceding eight months. The slight falling off in the level of export in the last few months of the season is a regular phenomenon, due to the availability of new crop supplies in the importing countries.

Owing to the large supplies in the exporting countries and the restricted demand of importing countries during the first eight months of the season,

the exportable balance on April 1, 1939 totalled about 756 million bushels, an extremely high figure, which, though not as large as the peak totals at this date between the years 1929 and 1934, was very little short of those figures.

*Exportable Supplies of Wheat on April 1, 1939.<sup>1</sup>*

(Million bushels)

COUNTRIES	Year 1937-38			Year 1938-39		
	Total exportable supplies	Net exports from August 1 to March 31	Remainder on April 1 1938	Total exportable supplies	Net exports from August 1 to March 31	Remainder on April 1 1939

<i>Total . . .</i>	<i>671</i>	<i>361</i>	<i>310</i>	<i>1,150</i>	<i>394</i>	<i>756</i>

(1) Supplies afloat excluded. — (2) Partly estimated.

On April 1 about a half of the exportable balance was concentrated in North America (U. S. A. 31 per cent. and Canada 18 per cent.); 27 per cent. was in Argentina, 13 per cent. in the Danube countries, 9 per cent. in Australia and the remainder in the other minor exporting countries. Except in Australia, exportable supplies in all the principal exporting centres on April 1, 1939 greatly exceeded those on April 1, 1938. Surplus stocks in Argentina in particular are abnormally high, and also those in the Danube countries.

In regard to the importing countries of Europe, imports in March rose considerably and were definitely higher than in March 1938. This sudden rise is due essentially to the United Kingdom, which imported 26 million bushels, the largest quantity imported in any one month since October 1931. But in spite of this increase, the total imports of Europe from August 1 to March 31 were only 10 per cent. more than the small total of the same period of last season.

The imports of the Continent during the first eight months of the season were exactly the same quantity as in the corresponding period of last season. Thus the increase for the European countries as a whole is due entirely to the increase in demand of the British Isles, where large reserve stocks are being accumulated. Owing to the slight decrease in stocks afloat destined for European countries on April 1 and May 1, it may be assumed that imports in the last few months of the season will average about 37 million bushels a month, so that the total forecast for European demand in 1938-39 will be almost exactly reached.

*Net Imports of Wheat into Europe (including flour in terms of wheat) \*.*  
(million bushels).

\* Aggregate net imports of normal importing countries, after deduction of exports, if any.

(1) Forecast March 1939. — (2) After deduction of net exports of 1 million bushels from Sweden and of 1 million bushels of net exports from Czecho-Slovakia. — (3) After deduction of net exports of 0.7 million bushels from Sweden. — (4) After deduction of net exports of 3 million bushels from Czecho-Slovakia. — (5) After deduction of net exports of 9 million bushels from Czecho-Slovakia. — (6) Denmark, Estonia, Finland, Latvia, Norway and Sweden. — (7) Czecho-Slovakia, Spain, Portugal, Albania, Malta, etc.

The imports of the extra-European countries show a considerable increase on last year owing to the large purchases of the Far East and the demand from India.

### The Condition of Standing Crops.

In last month's Crop Report, in summarizing the reports on the condition of standing crops in Europe at the beginning of April, we noted that the situation was very variable in different areas; it was unfavourable in several large producing countries of central and western Europe, but generally satisfactory in the south and east.

Crops were particularly mediocre in France, Germany, Belgium, the Netherlands and Poland, while in other countries wheat had resisted well the adverse conditions of the winter and spring, and their appearance was on the whole generally good. April was a very variable month: the first fortnight was fairly fine and sunny but the second was cold, stormy and wet. In the centre and west the fine weather of the first half of April caused a vigorous early growth of crops, which were considerably retarded, but the drop in temperature in the second

half of the month and the excessive moisture checked growth. In the south and east, where the dry and sunny weather had caused excessively rapid development and where there were some complaints of drought, rain in the third decade of April and the fall in temperature were very favourable. Thus at the beginning of May the condition of crops showed a fairly considerable improvement in most European countries, and the general tone of reports was satisfactory and promised for the continent as a whole an average, or slightly below average, production.

May opened with generally wet weather throughout the continent, precipitation being particularly heavy in the south. This precipitation was at first well received but later began to cause some preoccupation when it continued during the second decade of the month. At the same time the temperature remained rather low and there were very cold nights. These rather abnormal conditions do not allow a reliable estimate of crop prospects to be made. If the weather immediately turns fine with a slow and gradual rise in temperature, the crops of the southern and eastern countries may still be very large and those in other countries may be average. But if the bad weather persists or changes to warm weather too abruptly the wheat crop in Europe will be well below the average.

In regard to the other cereals, rye resisted the adversities of the winter and spring much better than wheat and its crop condition is generally reported to be satisfactory. The sowings of spring barley and oats were on the whole in good condition.

In the U. S. S. R. there were abrupt changes in temperature during April and in the first fortnight of May, but the rain which was particularly abundant and widespread had a beneficial effect on winter crops and created favourable conditions for the germination and growth of spring crops. Spring sowing proceeded in good conditions and at mid-May had made rapid progress. It seems that in a number of areas rye has not resisted the waves of intense cold which occurred during the winter and spring, when the fields had no snow cover; crop prospects are unsatisfactory. The damage suffered by winter wheat appears to be smaller and more or less limited.

In the United States the forecast of winter wheat production, made on May 1, gives a figure of 544 million bushels, which shows a small decrease of about 5 millions on the forecast made in the previous month. According to this estimate, the 1939 crop, though 21 per cent. below the excellent harvest of 1938, would be 9 per cent. higher than the previous five-year average. In the first half of May the mainly dry and hot weather was favourable in the east for the growth of crops, which made good progress, but was unfavourable for crops in the west, where there was drought. The small showers of rain which fell in this fortnight were limited to a part of the drought-affected areas and were not sufficient for growth. In the third week of May heavy rain fell in many parts, but its distribution was uneven and the benefit received was not very general. The first growth of spring crops took place in good conditions owing to the better sub-soil moisture reserves, but in a number of areas, following the spring drought, the need of heavy rain was beginning to be urgently felt.

The Canada the area that farmers intended to plant to spring wheat, according to the enquiry made by the Government on May 1, appeared to be practically the same as the area actually sown last year, (25,336,000 acres, compared with 25,188,000 in 1938). Sub-soil moisture reserves this year are more or less normal in most of the Prairie Provinces, but the small quantities of rain in April and in the first half of May were beginning to jeopardize the young crops, particularly in the south of the Wheat Belt. At the middle of May sowing was largely completed.

In India weather conditions were on the whole favourable for the last stage of maturation and for wheat harvesting. The second crop estimate, recently published, reflects, in fact, the improvement in prospects caused by the favourable weather. Total production is estimated at 365 million bushels, an increase of 20 millions on the estimate of last month. The new crop, though 30 million bushels smaller than the excellent production of last year, is 8 millions higher than the previous five-year average. Added to the large stocks left over from last year's crop, it leaves a total of supplies which is amply sufficient for internal consumption requirements during the coming season.

The condition of crops in Japan promises a more or less average production. In the near-Eastern countries large crops are expected.

In North Africa the prospects for a much better crop than last year were maintained, but in recent weeks there were complaints of excessive moisture, and it is feared that crops will be damaged following the appearance of a number of cases of rust. In Algeria the first forecast of production amounts to about 45 million bushels, against 35 millions last year and an average of 34 millions in the five preceding years. A very large production of barley is also forecast: 46 million bushels against 27 millions last year and an average of 34 millions. In Morocco an excellent crop is anticipated, and in Tunisia, in spite of the unfavourable weather of the beginning of May, about as large crop of wheat and a much larger crop of barley than last year are expected.

In Egypt, where also the wet weather was not entirely favourable for maturation, prospects continued to be satisfactory.

In the Southern Hemisphere preparations for sowing continued in Argentina in favourable conditions, but a decrease in the area under wheat is forecast. Operations for sowing are also well advanced in the various States of Australia, except in New South Wales, where they are hampered by excessive rain, and in Western Australia, where there is drought.

G. CAPONE.

### **Current information from various countries on Wheat, Rye, Barley and Oats.**

#### **Europe.**

*Germany:* The condition of sowings improved in April. Fairly serious damage is reported to have been done to crops during the winter, particularly to winter barley.

*Belgium:* Except in the first and last days of the month, which were sunny, April was cold and wet and generally unfavourable for agriculture. Winter cereals, which

had survived the frost, were growing unevelly. In a number of localities they were completely lacking in vegetation. A poor crop of all cereals may be forecast. Wheat re-sown early has a good appearance. In some cases very heavy manuring has been applied. Oats and barley crops are rising well.

*Bulgaria:* In April the weather was favourable for the growth of winter cereal. The sowing of spring cereals also was carried out in good conditions.

*Estonia:* Low temperatures prevailed in April and the rainfall was light. Although these conditions retarded growth, winter cereal crops were considered satisfactory.

*Finland:* The temperature in April averaged 2° F. above normal and the condition of crops is average. Spring sowing began at the beginning of May.

*France:* In the first half of April, there were in the country as a whole, a number of comparatively warm sunny days, interspersed with rains which ensured a vigorous new growth. In the second fortnight, the weather was wet and colder. During this period, growth was checked. Conditions were very different in the south with a cold and dry first fortnight and a mild and wet second fortnight; the nights were cool in this area and prevented crops from making up their considerable lateness of growth.

Winter wheat which survived the December frosts had, on the whole, at the end of the month, a better appearance than in March. The hot weather of April encouraged growth which was vigorous at the end of the month, but many fields were still patchy, thus allowing weeds to spread, the destruction of which was difficult owing to bad weather. "Alternative" or half season wheat, sown at the beginning of January in dry soils had a satisfactory appearance; but the later seedlings and those on wet soils were affected by cold and excessive rain. Spring sowings were carried out in good conditions and germination was regular. Reports confirm that seedlings carried out in January and February with "alternative" wheat and spring wheat have not made up the loss of acreage of winter wheat killed by the December frosts.

In regard to minor cereals, rye, which fully resisted the December frosts, had at the end of April made good growth. Winter oats which survived the frost were thin and weed-infested. It is already known that this crop was completely destroyed in the north and severely affected in other areas. On the other hand, the condition of spring oats and barley was excellent. The area is considerably increased, since these crops have partly replaced winter wheat destroyed by the frosts.

Thus, at the end of April, wheat crops showed an average or rather unsatisfactory condition and a rather reduced area. Prospects for rye, barley and oats, on the other hand, were on the whole satisfactory. The first fortnight of May was, on the whole, excessively wet and cold for this time of year and these conditions were not favourable for crops.

*Greece:* After the fine and mild weather of January, February and the first half of March, which was favourable for the sowing and germination of cereals, very wet and rather cold weather in the second half of March damaged crops but not to a very serious extent. The excessive moisture and cold weather checked growth. But in some cases, where crops were too far advanced, this check has had the good effect of averting the danger of lodging. Towards the end of March and in the first two decades of April the weather, having turned drier and warmer, began to cause drought. Later, at the beginning of the last decade of the month heavy rain throughout the country favoured growth, even in the south.

*Ireland:* Comparatively little rain fell during April, the weather on the whole being favourable for field work. The crops were in satisfactory condition on May 1

and no losses were reported. Spring cereals were sown under good weather and soil conditions.

*Italy:* In the first half of April there was a considerable rise in temperature and in some areas a shortage of rain. The growth of wheat and other winter cereals made favourable progress. In the second half of the month heavy rain mixed with hail fell, but the condition of wheat and other cereals remained good or very good in almost all districts.

*Latvia:* The temperature and precipitation in April were normal and at the end of the month the snow still remaining on the hills had melted. According to the reports of crop correspondents, the crop condition of winter wheat on May 1 was average in 48.5 per cent. of cases, above average in 44.0 per cent. and below average in 7.5 per cent. The corresponding figures for winter rye were 34.7, 62.4 and 2.9 per cent.

*Lithuania:* The weather was fine in April but the temperature was low. Strong winds and lack of rain were unfavourable for crops. The sowing of spring cereals had begun about the middle of April but was hampered by cold weather and wind.

*Luxembourg:* The generally low temperatures and excessive moisture of the second half of April retarded the growth of all cereals. The sowing of spring cereals was carried out in good conditions and was finished at the beginning of May, except in the case of barley.

*Netherlands:* Wheat crops suffered severely from the rigorous winter. The *Cereten* and *Mendel* varieties, which have the property of resisting cold better, were

† See explanation according of the various systems, page 411. — \* Countries not included in the totals. — (a) Above the average. — (b) Average. — (c) Below the average. — (e) Good. — (f) Average. — (w) Winter crop. — (1) Not including Austria. — (2) Acreage sown up to January 1. — (3) Middle of the month. — (4) Area indicated for harvest, calculated on farmer's intentions on March 1, 1939. — (5) Area harvested.

slightly less affected. In February winter wheat was still being sown, but for the most part spring wheat was used for resowing, though the latter gives a lower yield than winter wheat. Winter barley was mostly destroyed and that which was still surviving in the second half of April was in rather poor condition. The condition of winter rye is fairly good, as the crop was comparatively lightly affected by the winter frost.

*Poland:* According to the report of the Central Statistical Office, the second half of March was rather cold and wet. There were even several falls of snow and hoar-frost at night. At the beginning of April the north was still covered with snow. In the first half of April fine and much warmer weather stimulated the growth of winter cereals, particularly wheat, the crop condition of which improved considerably almost everywhere, except round Wilno and Nowogrodek, where the crop situation remained rather bad. The growth of winter cereals was estimated by 63 per cent. of correspondents as normal and by 37 per cent., particularly in the Wilno and Nowogrodek districts, as retarded. The sowing of spring cereals, though rather late, was carried out in good conditions. Sowing had not been begun only in the two afore-mentioned districts.

*United Kingdom:* The weather in April was very variable. In the first and last weeks there were cold north and east winds which in some places reached gale force. In the second and third weeks there were warm, sunny spells with high day temperatures but local night frosts. Sunshine was above normal, especially in the south. Rainfall was above normal in the south but below normal elsewhere.

Conditions were favourable on the whole for seasonal operations, but the cold spell towards the end of the month checked new growth. Wheat is generally a satisfactory plant., but both autumn and later sowings are still discoloured in a number of districts. Growth in Scotland was retarded owing to cold weather. Barley and oats were making fair progress at the end of April, re-seeding having been carried were necessary. Sowing conditions during April were mostly favourable and good seed beds were obtained, except on cold, heavy ground. Germination appeared to be generally satisfactory, but growth was retarded.

*Switzerland:* Weather was very variable in April. At times it was springlike and at the end of the month rather wet and cool. On the whole, conditions were not unfavourable for the crops.

Except for winter loss here and there, the winter cereals are thick and vigorous. In many areas, rye and barley were too thick and lodging may occur. Wheat is growing well, though in some districts the late sowings were adversely affected by the winter. Some damage was also done by spring-beetle larvae. On the whole, however, the condition of the winter cereals is promising.

Though somewhat late, spring sowing was favoured by the weather. Moisture was sufficient for normal germination and growth hitherto has been satisfactory.

Condition of spelt on May 1, 1939 was 85, in the system of the country, against 83 on April, 1, 1939 and 76 on May 1, 1938.

*Yugoslavia:* Cereal crops wintered well. There have been no serious floods, as last year. In fact, there was even drought in the Sava and Danube basins. The weather in March and April was generally fine and favourable for the growth of winter cereals.

*U. S. S. R.:* In the second half of April the weather was variable with more or less heavy precipitation in the north and centre of the European Territory. There

was also more or less heavy rain in same parts of Ukraina, Crimea and North Caucasus. Towards the end of the month and in the first decade of May a cold wave coming from the north brought cold and rainy conditions in the north, northwest and centre and had an unfavourable influence on sowing which slowed down towards the end of April and in the first decade of May, so that on May 10 the area sown to all spring crops was considerably smaller than the area sown to the same date last year.

*Area sown to all Spring Crops.*

» 10 . . . . .	148,325	72	158,155	75

In the first decade of May there was also heavy rain in the Caucasus, while in the south of Ukraina and the Transvolga region precipitation was light. In the south of the Union mild weather prevailed in the first decade of May. The rain that fell in the centre of the European Territory augmented soil moisture reserves, which are now sufficient for a normal growth of winter and spring cereals. In the south, particularly Ukraina, the reserves had diminished, but in the lower subsoil the quantity of water is still considerable. Reserves in the trans-Volga area are rather reduced.

On May 10 the condition of winter cereals in the north was satisfactory. In the centre it was variable, being often unsatisfactory in the case of winter wheat. Winter cereals were in good condition in Ukraina, Caucasus, Crimea and also in the provinces of Kursk and Orel in White Russia. In the south and west of Ukraina winter cereals were in process of ear formation.

In southern Ukraina, in Transcaucasus and in North Caucasus, spring cereals were at the stage of stem formation. Conditions were favourable for growth and most of the meteorological stations reported crop condition as being from good to excellent and only in a few cases satisfactory.

In Siberia the condition of winter cereals varied from good to excellent, as was also that of spring cereals in Central Asia.

## America.

*Argentina:* The sowing of cereals made good progress in April, except in the west of the grain belt, which was suffering from drought.

*Canada:* The Dominion Bureau of Statistics estimates from farmers' planting intentions that approximately 25,336,000 acres will be sown to spring wheat this year. This would be slightly above the average of the five years 1933 to 1937 and but little different from the area sown in 1938 (*See Table of Area and Condition of Cereals*).

The area sown to winter wheat in the autumn of 1938 is now estimated to have been 692,000 acres. The area remaining for harvest, after deduction of winter losses, as reported on May 1, is 657,000 acres. This would be 11.5 per cent. smaller than the 1938 area but 18.7 per cent. above the 1933-37 average.

The intended areas of oats, barley, rye and meslin are not substantially different from those of last year.

*United States:* The Crop Reporting Board estimates in its report as of May 1 that 38,936,000 acres of winter wheat remain for harvest of a total sown area of 46,173,000 acres. This indicates an acreage not to be harvested of 15.7 per cent., a proportion which, though higher than the abandonment of 1938, a very good year, is lower than the 1927-36 average abandonment of 18.2 per cent. The acreage not to be harvested includes not only winter killing but also diversion to other uses than grain, due partly to farmers' adjustments of their seeded acreage to their acreage allotments under the A. A. A.

The second forecast of winter wheat production is 326,357,000 centals (543,928,000 bushels). The final estimate of production in 1938 was 411,982,000 centals (686,637,000 bushels) while the average outturn of the period 1933 to 1937 was 298,260,000 centals (497,100,000 bushels); percentages, 79.2 and 109.4.

Subsoil moisture reserves were drawn on heavily in the Great Plains States during April and there was generally a lack of rainfall to replace surface moisture. Prospects in most of this area were somewhat below average on May 1. Slightly above average yields were indicated in parts of the Ohio Valley and of the Mountain States. May was expected to be a critical month.

The seeding of spring wheat, on a considerably lower scale than last year, was carried out in generally favourable conditions, but rainfall in April and May was much below normal and subsoil moisture early in May was becoming short. Temperatures in April were above normal. In both the northern Great Plains area and in the Pacific Northwest growing conditions were unfavourable in April and the crop on May 1 was largely dependent on good precipitation in the coming two months. Rye prospects were better than average on the whole, particularly in the North Central States.

Production of rye in 1939 is expected to reach 26,200,000 centals (46,700,000 bushels) as compared with 30,822,000 centals (55,039,000 bushels) in 1938 and with a 1933-37 average of 19,290,000 centals (34,447,000 bushels); percentages, 84.8 and 135.6.

Oats prospects in the Southern States were much poorer than last year in Texas and Oklahoma, but in the other Southern States were about equal to last year.

The weather was warmer and favourable in the east during the first week of May but rain was needed in the west. The winter wheat crops showed some deterioration, particularly in parts of Oklahoma, Texas and Kansas but conditions in the spring wheat states were generally satisfactory with seeding practically completed.

In the second week of May high winds intensified drought conditions over large areas in the west, but rain benefited parts of Kansas, Oklahoma, Texas and the Rocky Mountain regions. Generally low temperatures retarded germination and growth but farm work advanced rapidly. Progress of winter wheat was fair to good.

#### Asia.

*India:* In the last decade of April crop condition was reported to be on the whole fairly good. In the Punjab in April and the first week of May the weather was dry except for light showers. Crop condition at the end of that period was average to good in irrigated areas and under average to average in unirrigated areas. The crop was affected by rust in Lahore and by insects in Multan.

(Telegram of May 23): Production of wheat is estimated at 218,736,000 centals (364,560 bushels) against the previous month's estimate of only 206,640,000

(344,400,000). It shows a decrease of 7.5 per cent. on the corresponding estimate of 263,387,000 (393,979,000) in 1937-38 but an increase of 2.3 per cent. on the corresponding five-year average of 213,920,000 (356,533,000). According to a telegram received on the same date from the Government of the Punjab, production in that Province, which is included in the above total, is now estimated at 80,304,000 centals (133,840,000 bushels) against the previous months' estimate of 74,440,000 (124,100,000). It shows a decrease of 10.8 per cent. on the corresponding estimate of 90,003,000 (150,005,000) in 1937-38 but an increase of 3.3 per cent. on the corresponding five-year average of 77,768,000 (129,614,000).

*Japan:* Favoured by the weather of the first days of May, winter wheat and barley are in normal condition.

*Palestine:* Weather conditions were seasonable with rain during the first fortnight of April. Hot easterly winds, high temperatures and low humidity, changed quickly to cold conditions in the latter half of the month. Crops were not affected by sciroccos. No diseases were reported. There was heavy straw growth with well filled ears. Crop condition and prospects are excellent. The barley crop now in the course of being harvested is excellent, with a fine sample of grain.

*Syria and Lebanon:* There have been good rains and favourable weather conditions for the tillering of cereals. Some minor damage by field-mice is reported in certain districts. Crop condition is good.

## Africa

*Egypt:* Maturity of the wheat crop is progressing satisfactorily. Harvesting was started about the middle of April in Upper Egypt, where already one third of the crop has been harvested. In other localities, however, harvesting has only been started in limited areas. The crop is satisfactory. Harvesting of the barley crop is over in Upper Egypt and is general in other localities. Threshing and storing are in progress. The yield per acre is expected to be slightly above the average.

*French Morocco:* Rain, followed by a very sharp drop in temperature, occurred at the end of March and there was frost in the whole of north Morocco, affecting early crops in certain places. In April, the weather was variable, changes in temperature and wind being frequent; rain was of short duration but widespread.

The growth of wheat continued to be excellent, serious losses due to frost among early cereals and due to *cecidomyia* among late varieties being very localized. The ripening of soft wheat began in the south and hopes of high yields in the whole of Morocco will soon be realised if the weather is normal.

The harvesting of barley began in Chaouïa, Doukkala, Abda and Rehanma and the yields forecast are very much higher than the average of preceding years.

The condition of cereals on the whole is excellent.

*Tunisia:* In April the temperature remained below average and the sky was mostly overcast. Very heavy rain fell successively over the various parts of the country, particularly the south and far south. The heavy rain caused wheat lodging in certain areas (Souk' El Khémis and Béja). On the whole, however, on May 1 the crop condition of wheat and maize was good, that of oats very good and that of barley and rye excellent.

## Oceania.

*Australia:* Good rains over the greater part of New South Wales in March greatly improved conditions in the wheat belt. In parts of the southwestern slopes and Riverina, prolonged rain delayed preparations for the new crop, but sowing could safely be delayed for some time. In other districts work was well forward at the beginning of April.

Heavy rains in March in Queensland interrupted land preparation for the coming wheat crop, but provided valuable subsoil moisture reserves and ensured favourable conditions for seeding.

Moderate to heavy rains fell over the greater part of South Australia early in March, and land for the coming wheat crop greatly benefited.

March was dry and hot in Western Australia but following the heavy rains of mid-February, the soil was expected to be in good order for winter sowing provided good rains should come in April and May.

## Current information on Maize.

*Bulgaria:* The weather in April was favourable for seeding preparations and for sowing itself which is proceeding actively.

*Greece:* The preparation of the land, which had begun in good condition in January and February, was checked in March by bad weather, which would have the effect of delaying the sowing and growth of maize. But the return of fine and warm weather in April improved the situation.

*France:* The preparation of the land was in many cases hampered in April by the bad weather. The first fortnight of May was wet and cold and also unfavourable.

*Italy:* The weather in the first half of April was very favourable for the preparation of the land for maize sowing. In the second half sowing proceeded normally and the first germination was even.

*U. S. S. R.:* Maize was growing in good conditions in the south, where at the end of the first decade of May, crops had reached the stage of formation of the third leaf.

*Argentina:* In April the threshing of maize was in full swing. Results were considered as average on the whole.

*United States:* Maize planting advanced satisfactorily during the last week of April and the first week of May.

*Netherlands Indies:* Java and Madura. — The Department of Agricultural Statistics of the Central Statistical Office communicates the following details on the maize area:—

	1939 acres	1938 acres
Area harvested in March. . . . .	437,000	668,400
Area harvested from January 1 to March 31	2,374,000	2,273,200
Area of standing crops at the end of March.	680,000	642,700

*Indochina:* The crop was being harvested in March in Cambodia and Cochinchina with medium yields in nearly all parts. In Annam, growth was showing the effects of drought at the end of the month; yields will be considerably lower. Growth in Tonkin was good and husking was begun.

*French Morocco:* Maize sowing was carried on during April. The weather was favourable for crops and growth at the end of the month was quite satisfactory though

† The years indicated are those of the harvest, single years referring to the Northern Hemisphere, double years to the Southern. — \* Not included in the total. — § In calculating the totals account has been taken of the probable area cultivated in some countries for which estimates of production are available but not those of area. — (1) Including Austria. — (2) Estimate for the old territory. — (3) Area sown. — (4) Maize sown in spring. — (5) Maize sown in summer. — (6) Crop grown alone. — (7) Mixed crop. — (8) Average 1934 to 1936. — (9) Area fixed by the Plan. — (10) Average 1932 to 1935. — (11) Maize for all purposes. — (12) Maize harvested as grain. — (13) Including Tigris. — (14) *Nili* maize. — (15) *Sefi* maize. — (16) Cultivation by Europeans. — (17) Maize and sorghum. — (18) Area harvested. — (19) Cultivation by natives.

a few minor fields had to be resown owing to bad germination as a result of the drop in temperature at the end of March.

*Tanganyika:* Good progress with maize planting was reported in March from most districts.

*Tunisia:* The area under maize and sorghum in 1939 is estimated at 61,800 acres against 42,500 acres in 1938 and an average of 52,200 acres in 1933 to 1937; percentages, 145.2 and 118.3.

*Union of South Africa:* Prospects for maize crops in March in the Union as a whole were very promising. In the Orange Free State only light rains fell during the month. Provided no early frosts should occur, excellent crops were expected. There was sufficient rain and pleasant sunshine in Transvaal. Only a few parts of the western highveld were experiencing drought. Crop prospects were promising. In Natal the weather in March turned much cooler. Rain fell only locally, and good progress was made with cultivation. Prospects for good crops were enhanced.

### Current information on Rice.

*Italy:* The first half of April was very favourable for the preparation of the land for rice sowing. At the end of the month sowing was nearly finished.

*British Guiana:* In March the spring rice crop was being reaped, and returns were reported to be fair.

*Netherlands Guiana:* Owing to very heavy rain during almost all the growing season the yield per acre is below normal but the quality is fairly good.

*India:* In Bengal there was light to moderate rain in April and the first decade of May, at times inadequate for field operations. Good general rain was needed. In Bihar and in Orissa there was light rain. In Assam the weather was favourable in mid-April in the Surma valley but dry in the Assam valley, where rain was badly needed, but in the first half of May it was generally seasonable and crop conditions and prospects were fair.

In the Central Provinces the weather in April and the first week of May was hot, with cloud and localized light showers in the first three weeks but clear skies in the last fortnight.

In Madras there was rain over the whole of this period, on the whole moderate but very heavy in the Carnatic in the second week of April.

*Netherlands Indies:* Java and Madura. — The Department of Agricultural Statistics of the Central Statistical Office communicates the following details on the rice area:—

	1939 acres	1938 acres
<i>Area harvested in March:—</i>		
Wet padi . . . . .	473,200	479,000
Dry padi . . . . .	247,400	324,900
<i>Area harvested from January 1 to March 31:—</i>		
Wet padi . . . . .	793,000	791,000
Dry padi . . . . .	323,500	419,800
<i>Area of standing crops of the end of March:—</i>		
Wet padi . . . . .	6,727,300	6,681,600
Dry padi . . . . .	594,300	524,900

*Indochina:* The rice crop situation in March in the various parts of the Union, excepting Laos, was as follows.

The area under rice in Annam (first half-year) in 1939-40 is estimated at 1,075,500 acres against 1,180,000 acres in 1938-39 and an average of 1,020,500 acres in 1933-34 to 1937-38; percentages, 91.1 and 105.4.

In North Annam the growth of fifth-month rice continued very satisfactorily; tillering took place normally and flowering began among early crops. In Central and South Annam drought impaired crops, particularly fifth-month rice. Early crops, however, particularly third-month rice, yielded normal harvests. In the far south yields were mediocre owing to drought.

In Cambodia many further flooded-land crops were planted out. Dry-season rice was harvested; yields were passable on all lands which it was not possible to irrigate.

In Cochinchina rice harvesting was finished in almost all districts with satisfactory yields. Cultivation was begun in preparation for the 1939-40 rice season and for other crops.

In Tonkin, following favourable weather conditions, the growth of fifth-month rice was very satisfactory. Tillering was good everywhere; it had finished in fields planted out in December-January and was continuing in those planted out in February.

*British Malaya:* By the end of February in North Kedah the harvest was almost complete, and in the Central and South Districts was well in hand. After receiving reports on the areas so far reaped, considerable optimism was felt locally as to the total crop likely to be harvested and it was expected to exceed last year's by a considerable amount. During February weather conditions were dry and very favourable for harvesting. Over the greater part of Pahang the harvest was completed. Although weather conditions during part of the season were very unfavourable, the crop harvested was better than had been expected and some reports stated the yields to be greater than those of the previous season. General prospects for the 1938-39 season were confirmed to be good. It was stated that, summing up the general impression one obtains from district reports, it would appear that the area planted in Malaya in the current season is rather larger than last season, and that the crop harvested should be appreciably greater than in the 1937-38 season.

*Tanganyika:* It was reported in March that the yields of rice were expected to be poor except where it is grown under swamp conditions.

### **Current information on Potatoes.**

*France:* The preparation of the land was very often made difficult during April by unfavourable weather conditions. At the end of the month, there was a fairly considerable delay in planting. The first fortnight of May was wet and cold and also appears to have been unfavourable for crops.

*Greece:* The planting of early potatoes continued in March in spite of unfavourable weather. A return of drier and warmer weather in April, the increase in the area sown and the wider use of selected tubers indicate that the production of potatoes will be considerably increased.

*Italy:* In the first half of April the rise in temperature stimulated the growth of early potatoes. At the end of the month crop condition was good.

The area planted to early potatoes in 1939 is estimated at 79,800 acres against 84,600 acres in 1938 and an average of 73,300 acres in 1935 to 1937; percentages, 94.3 and 108.9.

*Argentina:* The lifting of potatoes in Buenos Aires Province in April gave variable and on the whole unsatisfactory yields. Crop prospects for late varieties varied from average to good.

*Canada:* According to the official report on farmers' planting intentions at May 1, the area under potatoes in 1939 will be about 522,000 acres. This compares with a planted area of 521,900 acres in 1938 and with a 1933-37 average of 527,400 acres; percentages, 100.0 and 99.0.

## General Review of the Condition of Sugar-beet Crops.

After a spell of spring weather in the first half of April, cold and wet weather returned in the second half of the month and this frequently interrupted the preparation of the land in nearly all the beet growing countries of Europe. But these conditions did not prevent sowing from being carried out in good time, and being largely finished before the end of April.

In the first half of May the weather continued cold and wet and had an unfavourable effect on sugar-beet crops. In central and northern Europe the growth of the young plants, which had perhaps been in advance of the normal slowed down owing to the lack of sun and to frequent, cold precipitation. !

The growth of crops, though slow and rather struggling, was still fairly even and crops were still, with few exceptions, more or less uniform, if weak. The weather was also unfavourable for cultivation, though the first hoeing was carried out almost everywhere.

The cold weather of the first half of May militated against the spread of insect pests, which are reported only in a few districts. Excessive moisture, however, encouraged the spread of weeds, which were particularly rife where rain had interrupted seasonal operations.

In southern Europe also, beet crops encountered unfavourable weather conditions. The bad weather and long rainy period, having found crops in a more advanced state than further north the damage was smaller; it was even estimated on the whole that, if the season should improve, crops might recover without difficulty.

The estimates of area under sugar-beet, published in the accompanying table, are mostly unchanged from last month. Some revision has been made only in the estimates for Germany, Bohemia-Moravia and Slovakia, Belgium, Lithuania, Romania and Yugoslavia. In Asia there have been added estimates for Manchukuo and Turkey. These modifications have been made on the basis of reports from the various governments, sugar manufacturing associations, or the International Society for Sugar Statistics.

The changes, however, have not involved any substantial alteration in the total of sugar-beet acreage.

*Acreage of Sugar-beet.*

**Current information on Sugar.**

*Belgium:* Sugar-beet crops are rather irregular and are affected by the cold weather of April.

*France:* The preparation of the land for beet sowing was in many cases made difficult by bad weather. Sowing was nevertheless finished at the end of the month, except in the north. In the north sprouting was slow and irregular owing to cold and the freezing of the surface crust of the soil caused by rain. The first half of May was exceptionally wet and cold and consequently still less favourable for crops.

*Italy:* In the first half of April the germination of sugar-beet was retarded here and there by lack of moisture. In the second half of the month also, growth was on the whole irregular.

*Production of Cane-sugar.*

(1) Approximate data.

*U. S. S. R.*: On May 5, 97 per cent. of the Plan of sugar-beet planting had been executed against 96 per cent. at the corresponding date of last year and consequently sowing was practically finished. In most producing areas germination took place in good conditions. In the south the first operations of cultivation had already begun.

*Argentina*: The condition of sugar-beet crops in April was good in the irrigated zones of Buenos Aires Province, while in some parts of Río Negro disease had damaged crops.

The condition of sugar-cane plantations in April was very good.

*Barbados:* During March weather conditions were less favourable than in February, only light showers being experienced.

*British Guiana:* The weather in March was favourable for the cane crop. All sugar estates were grinding and yields were reported to have been good, but it was expected that the total crop would be short, owing to the excessive rains of last year.

*Leeward and Windward Islands:* It was reported in March that in St. Kitts the young cane crop for next year was looking very promising. The sugar crop had already started in St. Lucia.

*Jamaica:* During March cane grinding was proceeding satisfactorily.

*Trinidad:* In March the weather continued ideal for the sugar crop, and the factories were being amply supplied with cane. Several cane fires were reported.

*Indochina:* Planting of green canes continued in Annam during March while planting of red canes was completed early in the month. Growth was good in Cochinchina where cane plantations have been substituted for pineapples.

*Mauritius:* The cyclone which passed near Mauritius on March 19 caused moderate damage; since then the growing conditions for the new cane crop were favourable.

*Australia:* Flood rains inundated many canefields in the northern sugar-growing areas in Queensland in March but reports indicate that the cane suffered little damage. Heavy rains in the Lower Burdekin district provided a respite from irrigation and replenished underground water supplies which had shown signs of receding. The southern sugar areas also benefited from the rains.

### Current information on Vines.

*France:* In the south, April was cold and dry in the first fortnight and mild and wet in the second fortnight, with variable conditions towards the end of the month. In other areas, the first fortnight of April was comparatively warm and sunny with occasional rain. The second fortnight was cold and rather wet and similar conditions persisted until May 15. The planting of vines was finished about the middle of April. Growth, on the whole, was about a fortnight later than normal. At the end of April, budding was general in well-exposed vineyards and was satisfactory. Cluster formation appears to be at least average in the most advanced vines. The damage done by the winter frosts, though rather serious in some cases, is more or less localized. Frost on April 30 in the South also did damage which appears to be limited and, on the whole, unimportant. The wet spring is giving rise to fears of a spread of mildew with the return of sunny and warm weather.

*Italy:* The growth of vines in April was good.

*Luxemburg:* The low temperatures and wet weather of April did not have any unfavourable effect on the growth of vines.

*Argentina:* The vintage was carried on actively in April with good results in the principal producing centres. In Mendoza yields are normal in spite of the damage done to vines by the October frosts. In the Río Negro Valley the production of grapes is on the whole satisfactory, though below normal.

Drought in San Juan has considerably reduced grape production. The yields in Jujuy and Salta are lower than last year. In Catamarca and La Rioja forecasts are generally good.

*French Morocco:* The end of March was wet with a very sharp drop in temperature. Frosts were reported throughout north Morocco. The weather in April was changeable with frequent variations in temperature and direction of wind; rain was of short duration but widespread. Vines, which had been well advanced, suffered from these sudden falls in temperature, but in many vineyards budding out only took place after the frosts and the loss, estimated at about 25 to 75 per cent. of the crop in Rharb, was not universal. But another frost of about  $-2^{\circ}$  to  $-3^{\circ}$  C. occurred at Meknes and Fès towards the end of April. This frost caused further losses, for growth was already advanced at that period.

*Tunisia:* In April the temperature remained below the average and the sky was mainly overcast. Very heavy rain fell successively in the different parts of the country. Owing to the alternation of rain and sun, the budding out of vines was rather late. Mildew and *oidium*, which had made an appearance were energetically combatted.

### Current information on Olives.

*France:* The first half of April was dry and cold and the second half mild and wet. Considerable progress was made with cultivation, which had been neglected for several years. The improvement is due to the good crop of 1938, to the high price of oil and to the measures taken by the Government. Moth was doing fairly serious damage to a large number of trees at the end of April.

*Italy:* The growth of olive trees in the first half of April was good and the blossom was satisfactory. At the end of the month crop condition was normal.

*Argentina:* The condition of olive trees in April was generally good. The yields obtained so far have been very satisfactory, as is also the market price of the new crop.

*French Morocco:* The weather in April was changeable with short but widespread rains and very sharp falls of temperature towards the end of the month. In the Fès area the blossoms and young shoots of the trees were completely withered by frost, with losses of the crop amounting to 50 to 100 per cent. Elsewhere, such as Meknes, trees were less advanced and were not affected.

*Tunisia:* Olive-trees, which had suffered from drought in the centre and south of Tunisia in the last few years, benefited from the winter rains. Their foliage recovered and, where they had not formerly been too seriously affected, an abundant blossom was anticipated at the beginning of May.

### Current information on Flax.

*Belgium:* The growth of flax is retarded owing to the cold weather of April.

*France:* In spite of the difficulties encountered in sowing owing to the rain and bad weather of April, flax rose rapidly and in excellent conditions. The first half of May, however, being cold and wet, does not seem to have been favourable for crops. It appears that the acreage under cultivation to flax is considerably larger than last year, and would thus reach on extremely high figure, almost double the average of the five preceding years. The increase appears to be due to the measures taken by the Government to encourage cultivation and to the high prices.

*Italy:* In the first half of April, the germination of flax was good and in the second half of the month growth was normal.

*U. S. S. R.:* On May 5 the area sown to Dolgunetz flax, i. e. for the production of fibre and grain on collective holdings, which represent practically the entire cultivation of this crop, amounted to 1,753,000 acres, or 40 per cent. of the Plan, against 1,692,000, or 38 per cent. of the Plan, at the corresponding date of last year.

Sowing was finished at this date in Ukraina and 84 per cent. was completed in White Russia.

*Canada:* According to the official report on farmers' planting intentions at May 1, the area under flax for seed in 1939 will be about 278,000 acres. This compares with a sown area of 221,200 acres in 1938 and with a 1933-37 average of 299,200 acres; percentages, 125.7 and 92.9.

### Current information on Cotton.

*Greece:* The preparation of the land, which had begun in good conditions in January and February, was checked in March by bad weather, which will delay the sowing and growth of cotton. But the return of fine and warm weather in April considerably improved the situation.

*Italy:* In the first half of April cotton sowing was begun in Southern Italy and Sicily. In the second half of the month sowing was general.

*U. S. S. R.:* Or May 5, cotton sowing, in spite of unfavourable weather in some cotton zones, was nearly finished. In the Union as a whole 4,773,000 acres had been sown, or 97 per cent. of the Plan, against 4,717,000, or 96 per cent. of the Plan, in the corresponding period of last year. In Tadjikistan, Turkmenistan and Kirghistan the sowing Plan has been fully executed, in Ukraina 99 per cent. and in Uzbekistan 98 per cent. Sowing continued. Crops are growing in good conditions both in the old cotton areas (Central Asia and Transcaucasus) and in the new (Ukraina, Crimea and North Caucasus).

*Argentina:* The excessive rain of the second half of March and the first decade of April retarded the maturation of cotton bolls and picking operations in the principal producing centres. In the Chaco the condition of plantations at the beginning of April was generally good, except in the west. The picking of early varieties gave low yields of average quality. Plantations in Corrientes and Santiago del Estero were damaged by excess moisture. The condition of plantations was still considered good in the other producing centres of the country.

*United States:* During the week ended April 19, dry and sunshiny weather was needed in the northern part of the cotton belt for field work. Temperatures were too cold in some of the central parts for good germination, but in most of the eastern portions planting continued active, and some cotton was coming up in Southern Georgia. The progress and condition of the crop in the extreme south and coast plains of Texas remained generally good, but the weather was too dry for growth in the south-western part of the State and for preparations in the west central areas. The progress of planting preparations in the extreme southern part of Oklahoma was slow. In the following week the planting in the eastern part of the belt made

good to fair advance rather generally. Chopping has begun in Southern Georgia and South Carolina. The progress of the cotton already planted in the lower Mississippi Valley was poor to fair, and much planting and replanting remained undone owing to the coldness of the weather and excessive soil moisture. The progress of planting in Oklahoma was slow. In Texas progress generally was poor, the weather being too cold for proper growth. During the week ending May 3, there was fair to good advance in cotton planting in the eastern part of the belt, extending well to the northern portions. Condition ranged from fair to good, chopping made good advance in South Carolina and fair progress in Southern Georgia. In central parts of the belt planting was well advanced in Louisiana while excellent progress in this work was made in the latter part of the week in Arkansas. In Oklahoma it was too dry for planting and progress was slow. In Texas planting made good advance, but only slow progress in the north-west of the State, as the soil was too dry. During the week ended May 10, mostly cold weather prevailed except in the extreme west,

Summary of the Cotton Reports  
issued by the Government of the United States, during  
the cotton season (August 1-July 31).

	Provisional estimates for dates indicated 1938-39	Final estimates		Percent. 1938-39	
		1937-38	Average 1932-33 to 1936-37	1937-38 = 100	Aver. = 100
Report referring to July 1:					
Area in cultivation (acres) . . . . .	26,904,000	34,471,000	32,752,000	78.0	82.1
Report referring to August 1:

Report of May 25:					
Revised estimates of the cotton crop:					
Area in cultivation, on July 1 (acres) . . . . .	25,018,000	34,471,000	32,752,000	72.6	76.4
Area picked (acres) . . . . .	24,248,000	34,001,000	29,962,000	71.3	80.9
Production 4) . . . . .	11,944,000	18,945,000	11,745,000	63.0	101.7
Yield of lint per acre, in lb. . . . .	235.8	266.9	179.8	88.3	131.2
Cottonseed produced (sh. tons) . . . . .	5,310,000	8,425,500	5,221,400	63.0	101.7

(1) Area in cultivation on July 1 less the ten-year (1928-37) average abandonment 2.1 per cent. — (2) Area actually harvested. — (3) Ten-year (1927-36) average. — (4) In bales of 478 lb. net weight and exclusive of linters. — (5) In running bales, counting round bales as half bales and exclusive of linters. — (6) Total abandonment after July 1: 1.7 per cent. — (7) Abandonment: 3.1 per cent. — (8) Counting round bales as half bales and exclusive of linters.

and north-western portions of the belt. There was a considerable amount of rain in the central and eastern sections, but showers were scattered and largely light in the west. Temperatures in Texas were too low for favourable growth, and rain was needed in most places. In the eastern part of the belt increasing warmth was decidedly favourable. During the week ended May 17, moderate to substantial rains were widespread in the cotton belt. Temperatures were unfavourably low in most of the northern sections. Good progress with planting was made in most sections, though the weather was too cool and wet in some eastern districts during the latter half of the week, and progress was slow in north-western parts of the belt.

*Indochina:* In March the growth of cotton was normal in Annam. Picking had even begun in Binh-thuân, yielding 270 to 360 lb. of unginned cotton per acre. In Cambodia picking was finished on the red-soil lands, yields being average.

*Egypt:* Sowing was finished at the end of April, i. e. at the normal time. North of the Delta it is reported to be completed a week earlier than last year. Weather conditions in April were on the whole favourable for the growth of the young plants. The percentage of re-sowing in the country as a whole has not exceeded 3 per cent. Re-sowing was necessary mainly among early crops in Delta South and in Middle Egypt, which were damaged by the changeable weather of March or by parasites. It is estimated that the area planted to cotton is smaller than last year by about 5 per cent. in Lower Egypt and 10 per cent. in Middle and Upper Egypt. The second dressing and irrigation are general, and also thinning and manuring among early and main crops. Crop condition generally is normal.

Cotton ginned up to the end of April in bales of 478 lb. net weight, was as follows:

Varieties	1939	1938	1937	1936	1935	1934	1933
Giza 7 . . . . .	381,945	477,903	391,310	262,504	198,463	91,202	33,738
Sakellaridis . . . . .	—	92,175	107,764	186,742	207,736	238,967	251,976
Other varieties above:							
1 3/8" . . . . . (1)	147,082	106,172	92,674	101,043	53,348	111,649	74,949
1 1/4" . . . . .	44,575	30,710	30,378	43,151	43,940	75,551	72,838
1 1/8" . . . . .	1,050,421	1,320,395	1,222,804	1,135,246	1,027,953	1,225,546	570,376
Total . . . . .	1,624,023	2,027,355	1,844,930	1,728,686	1,531,440	1,742,915	1,003,877
Scario . . . . .	34,041	35,281	42,234	39,895	34,143	33,993	23,100

\* Unofficial estimate. — (1) Including Sakellaridis.

*French Morocco:* Cotton sowing was almost finished in April in the Gharb.

*Nyasaland:* It was reported in March that the cotton crop was making a good recovery after the excessive rains.

*Tanganyika:* An increase in the acreage cultivated for cotton in the Northern, Tanga and Eastern Provinces was indicated in March. It was also reported that the improved conditions of the cotton crop in the Lake Province gave promise of better yields than at one time anticipated.

*Australia:* (Queensland) Cotton harvesting began early in March. A yield of between 14,000 and 15,000 bales is expected. Following two unfavourable seasons (about 9,600 bales last year and 8,500 the year before) this good result should help

the industry considerably. Rains in March delayed harvesting to some extent, but little damage was expected to result, except a possible lowering of grades of more advanced crops.

### Current information on Hemp.

*Italy:* In the first half of April hemp germinated well, and in the second half of the month growth was normal.

*U. S. S. R.:* On May 1 the sowing of southern (Italian) hemp had been carried out on an area of 205,000 acres, or 93 per cent. of the Plan. That of northern (Russian) hemp only on an area of 108,000 acres, or 9 per cent. of the Plan.

### Current information on Hops.

*Yugoslavia:* At the beginning of May the pruning of hops was largely finished. Spring cultivation was in full swing. Early pruned crops are growing very well. The weather is favourable for growth.

### Current information on Tobacco.

*Greece:* In Eastern Macedonia and Thrace, the germination of the seedlings took place in most areas under very favourable conditions in the first decade of April, except in the Department of Serrès and the mountains, where bad weather delayed germination until the third decade of the month. The growth of young plants continued normally; in the country they had reached a height of one and a half inches. During April, hoeing was carried on and also the second and third ploughing of the land under tobacco. In some parts, the appearance of "*Grylotalpa Vulgaris*" was reported over a fairly wide area and elsewhere of "*Phytophthora Nicotiana*". Treatment was applied in good time. Certain delay occurred in Central Macedonia owing to a snowfall during the second half of March and subsequent bad weather with low temperatures and frosts. The damage done was repaired by re-sowing where necessary with the assistance of a rise in temperature. In Western Macedonia, owing to the mountainous ground and bad weather, sowing was delayed until the beginning of March and was subsequently widespread and completed towards the end of the month, except in certain exceptional cases where seedlings were destroyed and the ground had to be resown up to the first decade of April. The "*Grylotalpa Vulgaris*" also did fairly serious damage this year to seedlings. In Thessaly and Phthiotis and Phokis, germination and growth of young plants was not normal, owing to bad weather which destroyed a good number of seedlings. Growth is proceeding more or less slowly owing to low temperature so that transplantation will be rather late. The condition of the plants is, in most cases, very good.

*Italy:* The weather in the first half of April was very favourable for transplanting tobacco. Transplantation proceeded also in the second half of the month.

*Cyprus:* A crop report for March states that the weather was unsettled during the month. The condition of seed beds was good however and transplanting was expected to begin early in April.

*Indochina:* In March picking of the leaves proceeded throughout the colony. Yields were fairly satisfactory in Annam and Cambodia and average in CochinChina.

*Nyasaland:* Harvesting on Native Trust Lands took place during March, the main picking in the Palombe areas beginning on March 15. The crop in the Central

Division was satisfactory, considering the unfavourable weather, and the Native Trust Land crop appeared to be more free from disease than the European and tenant-grown. In the Northern Province dry, sunny weather was experienced in the last twelve days of the month and the crop improved rapidly, but a large out-turn is not expected.

*Southern Rhodesia:* According to the March report on crop conditions in Southern Rhodesia, fine dry weather during the last week of the month ended the prolonged spell of incessant rains and sunless days. It is, however, unlikely that the improvement in the weather will have made any significant change in the total production of flue-cured or fire-cured leaf, as the bulk of the crop was harvested before the improvement could benefit the growth. Development of the Turkish-type crop was retarded by the continual rain and dull weather. It is hoped, however, that the later plantings will have benefited to some extent from the warm, dry weather that came at the end of March. No estimates of area or production are yet available, but a considerable increase in acreage over last season is reported.

*Tanganyika:* It was reported in March that the present season had been unfavourable for tobacco, in Iringa, the rains having come too late and being likely to cause disease in early plantings. In Songea, also, the transplanting of tobacco was delayed by dry conditions, and only a slight increase in production over 1938 was anticipated. The yield of tobacco in Biharamuho, where harvesting was commencing, was not expected to reach that of last year.

## Current information on Other Products.

### Cacao.

*Grenada:* It was reported in March that the cacao crop, which was nearly over, would be short.

*Gold Coast and Togoland under British Mandate:* MAIN CROP 1938-39. — By the end of March the crop was practically finished, very little cacao remaining to be marketed. The total exports for the six months October 1938 to March 1939 amounted to 453.8 million lb., including 31.3 million lb. carry over; net exports of the new crop were therefore 422.5 million lb. The quantity marketed during March was 31.3 million lb. bringing the total for the season to 612.6 million lb. distributed as follows: September 4.5, October 31.3, November 97.4, December 165.8, January 192.7, February 89.6, March 31.3. The stocks at the end of March were 190.2 million lb., including 107.8 at Ports and 82.4 at Up-Country centres. The crop situation on March 1 may be summarized as follows:

Already exported . . . . .	422.5 million lb.
Stocks . . . . .	190.2   "   "
In farmers' hands . . . . .	2.2   "   "
<i>Total . . . . .</i>	<i>614.9 million lb.</i>

The estimated total purchases at up-country centres give an aggregate total much below this figure.

The mean purity of farmers' cacao examined during March was 84.3 per cent., this low level not being abnormal for the last lots marketed at the end of the season. The effects on the general level is negligible as the small quantity handled can be subjected to re-conditioning before export.

The grade percentages from the farmers' lots, firms' grading, and check sampling at ports are summarized below.

*Grade per cent. during March 1939.*

	Farmers' cacao (360 lots)	Original sampling (44,244,000 lb.)	Check sampling at ports (80,734,000 lb.)
I . . . . .	24.2	40.5	39.5
II . . . . .	32.4	48.8	50.3
III . . . . .	28.6	10.2	9.9
Sub-grade . . . . .	14.8	0.5	0.3
	100.0	100.0	100.0

The average number of beans in the standard 14 cubic inches space bean count for all ports during March was 126.3.

MID CROP 1939. — The weather was generally favourable for the development of the mid crop and a few pods of all sizes were seen in the farms. Harvesting was beginning in some areas, but the bulk of the crop was expected to be ripe in June and July, decreasing in August and merging into the following main crop. In Ashanti and the Western Province small amounts were anticipated; the Central Province estimate was 6.7 million lb.; 26.9 million lb., forming the bulk of the crop, was expected from the Eastern Province; the Trans-Volta Area crop was estimated at about 4.5 million lb.

CROP ESTIMATES. — At a meeting of the Cacao Crop Estimates Committee held in Accra on April 11, 1939, the estimate for the main crop 1938-39 was increased to 270,000 long tons (604.8 million lb.). A preliminary estimate of the mid crop 1939 was given as 18,000 long tons (40.3 million lb.).

MOVEMENT. — Movement statistics for March were as follows:—

	March 1939 (thousand pounds)	March 1938 (thousand pounds)
Railway off-loadings, Takoradi . . . . .	21.4	0.9
Exports:—		
Takoradi . . . . .	26.9	2.3
Accra . . . . .	43.9	4.0
Other ports . . . . .	15.7	3.9
<i>All ports . . . . .</i>	<i>86.5</i>	<i>10.2</i>
Eastern Frontier . . . . .	1.1	0.0
<i>Total exports . . . . .</i>	<i>87.6</i>	<i>10.2</i>

## Tea.

U. S. S. R.: Tea picking has begun in Georgia, where almost the entire production of the U. S. S. R. is concentrated. It is estimated that the production of green leaf this year will amount to 95,000,000 lb. an increase of 14 per cent. on the 77,000,000 lb. harvested in 1938.

*Inaochina:* In March tea picking had begun in Tonkin. The crop was poor on newly pruned plantations. In Annam growth was satisfactory.

*Japan:* The tea crop was in normal condition in May.

*Nyasaland:* Reports in March indicated that tea was doing well, and growers expressed the opinion that the season would be profitable.

## World Statistical Situation of Coffee.

### I. World Production of Coffee.

From the point of view of world production the 1938-39 coffee season was characterized in the principal producing countries as a whole by weather conditions rather unfavourable to the crop, and in some important areas by attacks of disease reducing the volume of production. In addition, in some countries, especially in Venezuela, owing to the exceptional low price on the international market, growers abandoned part of their crop. In consequence of these unfavourable factors, world production in 1938-39, according to official estimates and the information at present available and the probable volume of the crops in the countries that have not indicated their estimates, has been distinctly small. Its volume is estimated at 5,011 million lb., the smallest for many years, apart from the exceptionally low figure of 1935-36; it is 465 million lb. below the figure of last season and 331 million below the average for the preceding five years.

In particular the contributions of the various continents to world production in the current season show a reduction with reference to 1937-38, except in Africa, and similar reduction on the five-year average. The most pronounced decrease in absolute figures is in South America, where the total crop is scarcely 3,777 million lb. against 4,206 million in 1937-38 and 4,120 million on the average for the preceding five years.

In Brazil the weather was rather unfavourable to the crop and the exhaustion of the soil in some districts, the damage caused by «Stephanadores» and still more the voluntary reduction by the growers, are the principal factors in the decrease generally reported with respect to the past season, for which an official estimate is still lacking. Taking account of these unfavourable factors and of the abandonment of about 250,000 acres since 1937-38, Brazilian production in 1938-39 may be estimated at 3,086 million lb. against 3,413 million lb. in the past season and 3,385 million on the five-year average. The figures for the export surplus of 1938-39, calculated by the «Departamento Nacional do Café», is 2,893 million lb. only, in consequence of the poor years, of which 1,952 million are derived from the State of São Paulo, 522 million from the State of Minas Geraes, 145 million from the State of Espírito Santo, 124 million from the State of Rio de Janeiro, 150 million from the States of Paraná, Bahia, Pernambuco and Goiás.

To this quantity there must be added for the current commercial season the stocks remaining from the 1937-38 crop in the States of São Paulo and Minas Geraes, amounting to 238 million lb. The total exportable quantity for the current commercial season is thus 3,131 million lb. against 3,368 million for the preceding season.

The crop obtained in 1938-39 in Colombia (562 million lb.), which is the second largest producer and exporter of coffee may be considered as abundant, since it approaches the record of 1937-38 and exceeds the previous five year

(1) Estimated production.

average by 46 million lb. In this country, apart from annual oscillations due to weather conditions more or less favourable to the crop, the volume of production generally shows a tendency to increase, which has for several years been considerable.

The exceptionally small crop obtained in Venezuela was scarcely half that of the preceding season, which fairly closely approached the average. The causes of this heavy reduction must be looked for in the rather unfavourable weather generally and still more in the particular economic situation of this country, where the exchange rates and wages are very high, both these elements having a heavy influence on the cost of production of coffee, placing it at a level much above the prices on the international market. Altogether total production of coffee in South America in 1938-39 (3,777 million lb.), in consequence of the poor crops obtained in Brazil and Venezuela, shows a very appreciable diminution on both the 1937-38 production (10.2 per cent.) and the average for the preceding five years (8.3 per cent.). The proportion of the production in 1938-39 of all the South American coffee producing countries with reference to the world production is 75.4 per cent. against 76.8 last season and 77.1 during the five-year average.

In Central America the weather at the time of flowering and during the different phases of vegetation in the present season has not, on the whole, been very good. The available figures for actual production of coffee in 1938-39

In Salvador production in 1938-39 exceeds by about 20 million lb. the poor crop of the preceding season, which was seriously damaged by the unfavourable weather, and approaches fairly closely the average, without, however, attaining the level that would be expected from the great extension of the area.

\* Unofficial estimate. — (1) Exports. — (2) Export figures compiled from the statistics of French Somaliland and Anglo-Egyptian Sudan.

The crop in Guatemala in 1938-39 may be considered as abundant, since it exceeds by about 9 million lb. the average of the five years ending 1936-37, without, however, attaining the exceptionally high figure of 1936-37. With respect to the preceding season the decrease is only 7 million lb.

The information available for Mexico indicates a somewhat small crop, below the already small one of last season. It should be about the same size as that obtained in 1933-34. which was exceptionally small.

The estimates of the surplus exportable from Haiti during the commercial season of that country, which ends on September 30, 1939, indicates a figure coinciding with that of actual exports in the past season (55 million lb.), though

13 million lb. below the average export of the preceding five years. This year's reduction may be attributed to the unfavourable weather in the principal producing districts.

The crop in Cuba, estimated at 68 million lb. by the "Instituto Cubano de Estabilización del Café" approaches fairly closely the figures of last season and the average, oscillating around 71 million lb. The slight decrease is due almost exclusively to the Province Oriente, which is responsible for nearly 95 per cent. of the total crop.

The production estimated for 1938-39 in the Dominican Republic is very near the five-year average ending in 1936-37 though much below last season's maximum of 62 million lb.

Finally, in consequence of the damage due to excessive rain, the estimates of export surplus in Costa Rica and Nicaragua for 1938-39 show a decrease, particularly marked for the former country, with respect to both the actual exports of last season and the average.

Altogether, the production of coffee in Central America in 1938-39, estimated at 613 million lb., can only be regarded as mediocre since it remains 20 million lb. below last year's figure and more than 35 million lb. below the five-year average. Nevertheless the proportion of total production of these countries to world production is 12.2 per cent., exactly the same as that of the five-year average ending in 1936-37 and slightly above that of the last season. The American continent as a whole supplied in 1938-39 87.6 per cent. of the world production against 88.4 last season and 89.3 per cent. on the average for the preceding five years.

In Asia the results of the present season have been distinctly small; the total production is estimated at 282 million lb., i. e. 66 million lb. (18.5 per cent.), below the 1937-38 figure and about 31 million (9.7 per cent.) below the five-year average. The reasons for this exceptional contraction may be found both in the unfavourable weather and in the abnormal situation on the international market.

In the Netherlands Indies, which normally supplies four fifths of the total production of Asia, the crops both on European plantations and on Native plantations show a heavy decrease, more marked on European plantations. In fact the crop from these plantations is 28 per cent. smaller than that of last season and 22.5 per cent. below the average of the preceding five years; on the other hand the reduced production of Native plantations is only 15.2 per cent. and 1.2 per cent. respectively. The information available for India leads to the expectation of an average crop, about 35 million lb., slightly smaller than that of 1937-38. The proportion of the production of Asia to the world total in 1938-39 is 5.6 per cent. against 6.3 per cent. in 1937-38 and 5.9 per cent. in the five-year average.

Africa is the only continent in which the total production of coffee in 1938-39 shows a fairly appreciable increase with respect to the preceding year. After a progressive annual increase the production of this continent in 1938-39 attained the maximum of 326 million lb., thanks partly to the various protective measures accorded to native planters and to preferential tariffs given by the majority of

the countries with colonial possessions. The increase shown by this year's crop is 49 million lb. or 17.5 per cent. with respect to 1938-38 and 57 million lb. or 32.1 per cent. with respect to the average. The proportion of the production of this continent with respect to the world total has risen from 4.6 per cent. on the average of the five years ending 1936-37 to 5.1 per cent. in 1937-38 and 6.5 per cent. in 1938-39.

### International Trade in Coffee.

*Exports from the principal Exporting Countries.* — The most interesting and without doubt by far the most important aspect of the current coffee season is the commercial one, owing to the evolution of the international trade in the product following the new monetary and commercial regime adopted by Brazil at the beginning of November 1937. In face of the increasingly marked contraction in its exports of coffee and the steady increase in those of "mild sorts", Brazil on November 3, 1937 abandoned its policy of valorization of the product and returned to the regime of free competition, already attempted in 1933 but soon abandoned. The principal object of this reversal of Brazilian coffee policy was the increase of its exports to the highest level. The corollary of this new commercial regime was the price war. The principal measures adopted by the Brazilian Government to realize its programme of commercial expansion for coffee have been the reduction of the export tax from 45 to 12 milreis per bag of 60 kg., the abandonment of the unilateral defence of prices, the abolition of all Government intervention on the market, the suspension of restrictions on the exchanges and on trade in foreign currency, and the re-establishment of free trade. Since then the coffee battle has continued without ceasing and, despite already considerable developments, it is not possible to foresee with any exactitude its final results owing to the numerous factors intervening in the struggle.

(1) January-March 1939.

While the international coffee market is dominated by this new trade orientation imposed by Brazil, it is interesting to examine the situation with more precision and particularly the movement of exports from the two principal protagonists, Brazil and Colombia.

In Brazil the exports of the first half of the 1937-38 season (July 1-December 31 1937), which is the last period of the coffee valorisation policy, fell to the lowest level for many years, except in those of the corresponding half-year of 1932-33, when movements of the crop were disturbed by the Paulista Revolution of 1932: scarcely 783 million lb. against 981 million lb. on the average ending 1933-34 and 1,116 million lb. and 933 million lb. respectively in the same period of the season 1935-36 and 1936-37.

Movement in the second half of the 1937-38 season (January 1-June 30 1938), was on the contrary very active, thanks to the new commercial policy adopted by Brazil, exports attaining the figure of 1,151 million lb., which distinctly exceeds the corresponding exports in a long series of years except for the maximum export for 1930-31.

With respect to the corresponding figure of the preceding season the exports of the latter half year show an increase of about 330 million lb. Nevertheless the total exports of 1937-38 estimated at 1,993 million lb., exceeds the 1,754 million lb. exported in 1936-37, though it remains below the average exports for the five years ending 1933-34 (2,008 million lb.). In the first half of 1938-39 (July 1-December 31 1938) Brazilian exports remained at an exceptionally high level, attaining 1,121 million lb., a figure slightly exceeding the maximum of the same period in 1935-36 (1,116 million lb.). Exports in the first quarter of the current year (January 1-March 31 1939) show on the contrary, a fairly appreciable reduction with respect to the corresponding figure of last year: 480 million lb. against 559 million lb. It must however, be noted that despite the fact that the total exports of the first nine months of the current commercial season (July 1 1938-March 31 1939), with 1,601 million lb., exceeds by about 265 million lb. the quantity exported in the same period of the preceding season, the figures of monthly exports show a tendency to decrease. In fact the average monthly export in the second half of 1937-38, which was 192 million lb., fell to 187 million lb. in the first half of 1938-39 and to 160 million in the first quarter of 1939.

Total exports of Colombia in the commercial season 1937-38 (July 1 1937-June 30 1938), were 532 million lb., exceeding by more than 110 million lb. the average exports of the five years ending 1933-34 and approaching fairly closely to the maximum of the preceding season. In this connection it should be observed that the exports in the second half of 1937-38 (January 1-June 30 1938), that is, in the full tide of the commercial war, attained a maximum of 283 million lb. exceeding by 11 million lb. the already high figure of the preceding season.

■ During the first half of the current commercial season (July 1-December 31 1938) the export of coffee from Colombia attained a new maximum of 283 million lb. against 252 million lb. in the same period 1937-38. Amongst the favourable factors contributing to the increase in Colombian exports, especially in 1938,

(1) January-March 1939.

is the small amount of available "Milds" for export, in consequence of the poor crops obtained in 1937-38 in Salvador and some other producing countries of Central America. The exports of the first three months of the current year (January 1-March 31 1939), estimated at 117 million lb., shows on the contrary a decrease of 33 million with respect to the corresponding figure of last year. However, the total quantities of coffee exported in the first nine months of the current commercial season (July 1 1938-March 31 1939) shows a decrease of scarcely 11 million lb. on the corresponding figure of the preceding season.

The movement of coffee from the other countries producing "Milds" in Central America in the first half of the current commercial season shows on the whole with respect to the same period of 1937-38 a fairly appreciable decrease in consequence of the fall in exports from Salvador, Venezuela, the Dominican Republic and Costa Rica.

The exports from Netherlands Indies were also heavily reduced in the first half of the current season, but those from India showed a slight increase with respect to the same period of the preceding season. Finally all the producing countries of Africa except Tanganyika increased their exports in the first half of the season, thanks to the preferential customs regime that is enjoyed by the colonial possessions of the majority of European colonial powers.

*World net Coffee Imports.* — The world net import of coffee in 1938, estimated at 3,801 million lb., exceeds by 473 million lb. the figure of last year, which approximates fairly closely to the average net imports of the five years ending 1936. With respect to the maximum of 1935 (3,528 million lb.) the increase of last year is over 270 million lb. Europe and the United States, which are by far the principal markets, raised their net imports of coffee to an exceptionally high level in 1938. However, the proportion of this increase registered in Europe remains very much below that registered in the United States. The net import

of coffee into Europe, with annual oscillations that are on the whole of little importance, remained almost unchanged in the ten years 1927-36, the average of the two five year periods ending respectively in 1931 and 1936 were of the same size (1,460 million lb.). In 1937 there was an increase of about 40 millions in the net imports of this continent with respects to the preceding year. The already high figure of 1937 was in turn exceeded by about 126 million lb. in 1938, which also showed, with 1,645 million lb., an absolute maximum in the supplies absorbed by that continent.

1) Calculated figure.

In the United States where the import of coffee is not subject to customs duties, supplies absorbed in 1938 reached a still larger figure, and, like those of Europe, attained an absolute maximum with 1,979 million lb. This figure exceeded in fact, by more than 290 million lb. the net imports of 1937 and by about 370 million lb. the average of the five year of period ending 1936. In 1938 the United States thus absorbed 52.1 per cent. of the world net imports, against 50.7 per cent. in the preceding year and 46.7 per cent. and 48.3 per cent. on the average of the five-year periods ending respectively in 1931 and 1936. On the contrary, Europe imported in 1938 43.3 per cent. of the world total, a figure that, despite the very appreciable increase in absolute value, remains below not only the proportion of the preceding year (45.7 per cent.) but also the proportion of the two preceding five year averages (43.7 per cent. 44.9 per cent.). Finally, the net imports of the rest of the world, which in the above table has been grouped under Other countries, was estimated in 1938 at 176 million lb., an increase of 51 million lb. on the 1937 figure. Nevertheless the total imports of these countries of which the consumption is very limited remains more than one third below the almost identical figures of the two five year periods ending respectively 1931 and 1936.

Examining in detail the net imports of coffee of each of the seventeen European countries shown in the following table, which in 1938 absorbed 98 per cent. of the total imports of the continent, it may be observed that save in Italy, which in 1938 decreased its net imports with respect to the previous year and in Belgium and the United Kingdom, which maintained them at the 1937 level, all these countries increased their purchases of coffee. The most marked increase was in Germany of which the net import in 1938 (not including Austria) was 435 million lb. against 392 million lb. in the preceding year, which was a postwar maximum. With reference to the almost identical figures of the two five year averages ending respectively 1931 and 1936 (315 million lb.), the net imports

<sup>1)</sup> Calculated figure.

of that country in 1938 rose by about 120 million lb., thus slightly exceeding the average level of pre-war imports.

The net imports of France, which now takes the second place amongst European importers, were maintained in 1938 within the limits of the quotas,

which for some years have oscillated around 419 million lb., with an increase of about 8 million with respect to the preceding year (411 million lb. against 409 million in 1937). The most notable fact in regard to the supplies available for that country is the increasing proportion of coffee coming from the colonies, for which the figures rose from 42 million lb. in 1936 to 88 million in 1937 and 132 million in 1938. The contribution of colonial coffee to the supplies of the metropolitan country in 1938 thanks to the colonial preference of 202 Frs. per 50 kilograms and to the action of the Committee for Price Control in favour of mixing, thus reached almost one-third of the net imports of France, reducing by an appreciable amount the supplies from other countries. It should be observed that the first place amongst the French colonies is taken by Madagascar, which in 1938 supplied 78 million lb. against 56 million in the preceding year and 44 million in 1936. French West Africa follows with an equally important increase: 13 million lb. in 1936, 19 million in 1937 and 30 million in 1938. The supplies from other colonies and territories under mandates also show in the last few years a fairly marked tendency to increase.

Net imports of Italy, which in 1937 were maintained at the same level as the five years ending in 1936 (84 million lb.) decreased slightly in 1938. However, with respect to the average imports of the five years ending 1931 there was a decrease of 23 million lb. Amongst the other principal European importing countries, Sweden, Netherlands, Denmark, Finland, Norway and Switzerland showed a fairly appreciable increase in their purchases in 1938 with respect to both the preceding year and the average. The net import of coffee into the seventeen European countries as a whole, shown in the above table, thus exceeded by more than 119 million lb. the 1937 figure and by about 185 million lb. the absolutely identical figures of the two five-year averages ending respectively in 1931 and 1936. All the extra-European countries comprised in the above table also increased their net imports in 1938 with respect to 1937, and, except Japan, with respect to the average of the preceding five years. Imports into Argentina rose progressively from 46 million lb. on the average of 1932-1936 to 50 million in 1937 and 61 million in 1938. The increase in the imports of Canada, South Africa and Algeria is less marked than in the case of Argentina.

Years	Net world imports (million lb.)	Exports from Brazil	Percentage of total %
<i>Average 1909-1913</i> . . . . .	2,343	1,672	71.4
<i>Average 1927-1931</i> . . . . .	3,262	2,022	62.0
1932 . . . . .	3,166	1,579	49.9
1933 . . . . .	3,280	2,045	62.3
1934 . . . . .	3,213	1,871	58.2
1935 . . . . .	3,528	2,028	57.5
1936 . . . . .	3,511	1,876	53.4
<i>Average 1932-1936</i> . . . . .	3,340	1,880	56.3
1937 . . . . .	3,328	1,603	48.2
1938 . . . . .	3,801	2,264	59.6

The part played by Brazil in the world supply of coffee, despite the general tendency to increase net world imports in the last few years, underwent a progressive and very appreciable decline up to 1937, from 71.4 per cent. on the average of 1909-13, 62.0 per cent. in 1927-31, 56.3 per cent. in 1932-36 to 48.2 per cent. in 1937. In 1938 Brazil marketed 2,264 million lb. out of a world total of 3,801 million, that is 59.6 per cent., exceeding not only the low proportion of 1937 but also that of the preceding five years (56.3 per cent.). Parallel to the regression in Brazilian exports the countries producing and exporting "Milds" increased their absolute and relative contribution so as to attain maximum figures in 1937. In 1938 the proportion from these countries underwent a contraction, which was fairly appreciable with respect to recent years; however, it must be noted that this was not due to the abnormal conditions on the international coffee market in consequence of the commercial war, but rather to the small supplies of "Milds" available for export from the poor harvest of 1937-38.

### Measures adopted for the Stabilization of the Coffee Market.

The exceptional conditions on the world coffee market in November 1937 compelled the majority of the countries producing and exporting coffee to maintain and in some cases to extend during the current season the measures of protection adopted during the preceding season.

In Brazil, at a congress of the States producing coffee held under the auspices of the "Departamento Nacional do Café" in May 1938, it was decided to adopt a series of measures for the re-establishment of statistical equilibrium between exports and the capacity for absorption of the world market, at the same time regulating the arrivals of coffee at the ports of export. These measures may be summarized as follows:

(1) For shipments of coffee of ordinary or current quality (Despachos comuns), there were established three quotas namely: (a) equilibrium quota, so-called D. N. C. quota 1938-39, corresponding to 30 per cent. of the total, which must be delivered for compulsory destruction, to the Departamento Nacional do Café at the price of 2 milreis per bag of 133 lb. gr. weight; (b) retained quota 1938-39, corresponding to 30 per cent. of the total and applied to coffee retained for an indefinite time for sale at a favourable time; (c) direct quota 1938-39, corresponding to 40 per cent. of the total and applied to quantities for direct delivery to ports of export.

(2) For deliveries of superior quality (despachos preferenciais) the quotas fixed are two: (a) equilibrium quota, so-called D. N. C. quota 1938-39, corresponding to 15 per cent. of the total to be obligatorily delivered for destruction to the Departamento Nacional do Café; (b) preferential quota 1938-39, corresponding to 85 per cent. of the total that must be obligatorily delivered to the Departamento Nacional do Café for direct delivery to the ports of export.

The D. N. C. quota must be for coffees not inferior to type with a maximum of three per cent. of impurities.

Arrivals at ports of shipment were regulated by the D. N. C. so that the respective stocks were maintained within the following limits (million lb.): Santos 291; Rio and Nitcheroy 93; Victoria 40; Paranagua 15; Angra do Reis 8; Bahía 8; Recife 7; a total of 462 million lb. of available stocks.

In addition the Congress of coffee producing States confirmed the prohibition of new plantations in the national territory and set up general rules for the guidance of the coffee policy of the country. These rules had in view continuation in the interior of the practice of destroying surplus coffee from the new crop and, as regards the international situation, the continuation of the commercial struggle. The destruction of coffee since 1931, with elimination varying very greatly from one year to another had become a permanent institution in the coffee policy of Brazil.

*Quantities of Coffee destroyed in Brazil by seasons.*

(ooo pounds)

Season (July 1-June 30)	Production	Quantities destroyed			Percentage of production
		First half-year	Second half-year	Total	
					%

1937-38	3,412,547	1,223,790	693,377	1,917,367	56.2
1938-39	3,086,482	365,307	(3) 115,743	...	...

(1) Seven months. — (2) Thirteen months. — (3) Three months: January to March 1939.

It reached its maximum in 1937-38 with 1,917 million lb. against 1,141 million in the preceding season, which approached the maximum of 1933-34 (1,460 million lb.). In relation to the volume of the crop the percentage in 1937-38 (56.2 per cent.) was the highest since 1931-32, distinctly exceeding the maximum of the preceding season (41.4 per cent.). In the first half of the current season (July 1-December 31 1938) the rate of destruction showed a very marked slackening, attaining scarcely 365 million lb. against 1,224 million in the corresponding half year of the preceding season. Compared with the corresponding half year of the preceding season, the quantity of coffee eliminated from the market in the first half of the current season was the smallest since the beginning of the destruction policy, unless for 1935-36. The tendency to reduce the destruction was intensified in the first quarter of the current year (January 1-March 31 1939), the corresponding figure attaining only 116 million lb. against the 368 million eliminated in the same period of 1938. The excess stocks of coffee eliminated in Brazil from 1931 to the end of March 1939 reached 8,709 million lb., a quantity exceeding by about 130 per cent. the exceptionally high figure of world net imports in the past year. The elimination of coffee will be carried on in the 1939-40 season also. At the annual Congress of coffee producing States

last February, held under the auspices of the D. N. C., a resolution was adopted to maintain in 1939-40 a regulation identical with that of the current season, especially as regards the distribution of shipments, the proportions to be sold at the different prices, the buying prices and the regulation of deliveries at the ports of exports. In addition the existence of the D. N. C. was prolonged until June 30 1941.

The emergency measures adopted by Colombia for the mitigation of the effects of the fall of prices on the international market were as follows: a reduction from 12 per cent. to 10 per cent. in the tax on foreign exchange derived from preferential exports and the assignment of part of this profit to the «Federación Nacional de Cafeteros»; the regulation of the trade in foreign exchange and the control of exchange rates, propaganda for the increase of internal consumption of coffee. In Venezuela the Government had granted a premium of 22 bolivras per bag of 101 lb. of coffee exported and, to attenuate the disastrous effects of the poor unit-yields obtained in 1938-39, has authorized the Agricultural Bank to grant special credits to coffee growers who have lost more than 50 per cent. of their crops.

In Salvador the Government has reduced the export tax on coffee from 2.7 American Gold dollars to 95 cents per 220 lb., so as to favour the movement of the product which represents more than 90 per cent of total value of its exports.

The Government of Cuba, after having regulated the processing, transport and consumption of coffee within the country, establishing a minimum selling price, has granted a premium of 25 centavos per bag of 101 lb. of exported coffee. Finally all the countries producing and exporting coffee, so as to ensure the movement of their exportable crops at the low prices of the international market without excessive loss to the growers have had to maintain or initiate during the current commercial season a great many measures arranging from the reduction of export taxes to the concession of bounties and from the modification of their monetary policy to the granting of loans or a declaration of moratorium. The situation in colonial countries has been on the whole relatively more favourable in view of the privileges accorded to the entry of their coffee into the majority of the European countries having colonial possessions. In the international sphere must be mentioned the strong publicity campaign organized in the United States by the Pan-American Coffee Office of New York for the increase in consumption in that country and for the popularization of iced coffee.

### Prices.

The prices in Gold Frs. per quintal of the Brazilian variety Santos No. 4 and Rio No. 7 at New York and for Colombia at Le Havre, underwent a sudden and very severe collapse in consequence of the policy adopted by Brazil at the beginning of November. As regards Santos No. 4 in particular the average prices from that month onwards showed a steady and very appreciable decline to a minimum in April 1938. Since then, with slight monthly oscillations, prices of this variety, though remaining very much below the corresponding prices of 1937, have shown a slight recovery.

The November price, which is the highest of the year except for January, remains more than one-quarter below the average price of 1937 and 10 per cent. below the exceptionally low average of 1935. In December 1938 the price of this variety again showed a tendency to decline and the fall continued without interruption during the first four months of 1939.

*Prices of Coffee "Santos No 4" and "Rio No. 7" at New York  
and "Colombien" at Havre.*

(Price in gold francs per quintal)

Annual average	Santos No. 4 at New York	Rio No. 7	Colombien at Havre
1928 . . . . .	264.94	188.75	307.68

December . .	59.05	53.58	...	42.18	35.83	...	65.89	79.24	...

For Rio No. 7 at New York the decline in prices from November 1937 continued without interruption until May 1938, when the average price showed a reduction of 50 per cent. with respect to the corresponding price of the preceding year. A slight improvement then characterized the price of this variety until November 1938. However, from December onwards, both this price and that of Santos No. 4 again showed a slight decline which continued until last April. The prices of Colombia at Le Havre, with oscillations that were, however,

as violent as those of Brazilian varieties, declined fairly appreciably from December 1937. The minimum price of this variety corresponded in May 1938 to a reduction of about one quarter with respect of the price of the same month in the preceding year. From June the recovery was progressive and continued without interruption until February of the present year, the average price of which exceeded by 17 per cent. the average of 1938 and slightly exceeded those of the preceding two years. The prices of the following two months remained unchanged from the level of February 1939.

### Conclusion.

The conclusions of a general character that emerge from this summary review of the world statistical situation of coffee in 1938-39 and of the stage reached in the commercial struggle at present in progress and the countries producing "Milds" may be summed up as follows.

Although the production of coffee in 1938-39 was the smallest for many years, except in 1935-36, it exceeded by 1,210 million lb. the exceptionally high figure of world net imports in 1938. For several years there has been a crisis of over-production of coffee that the fairly constant increase in world demand has attenuated only to a very small extent.

At the beginning of November 1937 Brazil, after the failure of the Pan-American Conference at Havana, reversed its traditional policy of protection and valorization of coffee. Since then a commercial struggle has been engaged in between Brazilian coffee and "Milds". At the end of the first year of struggle the results were considered very satisfactory both in Brazil and in Colombia, which play an absolutely predominant part in the world supply of coffee. The quantity of coffee exported in 1938 by Brazil exceeds in absolute figures by about 660 million lb. or (41.2 per cent.) the exports of the preceding year and by 384 million (20.4 per cent.) the average movement of the preceding quinquennial period. Despite the very appreciable fall of prices the commercial results of the first year of the new policy were considered in Brazil to be generally very satisfactory, since they permitted a lightening of the internal market and an appreciable decrease in the destruction of coffee. Colombia, thanks also to a somewhat small export surplus of "Milds" in 1937-38, has entirely exported its surplus at relatively satisfactory prices.

The other countries producing "Milds" were also able to market their entire exportable surpluses in 1938. However, the problem of coffee remains unsolved owing to the impossibility at the present time of the re-establishing of even an approximate equilibrium between world production and consumption. The measures of urgency adopted by the majority of producing countries without doubt attenuated the repercussions of the commercial disturbance that at present affects the world market for this product, but a permanent solution remains dependent on solidarity amongst the producing countries. Such a firm entente which must in the first place regulate production and the commercial distribution of coffee in the world is the indispensable basis for a wider international agreement, to

which all the principal countries consuming coffee would adhere. The participation of these would facilitate the elimination or the reduction to a minimum of the obstacles that limit, with international trade, also the world consumption of coffee.

A. DI FULVIO.

### Current information on Coffee.

*Indochina:* Harvesting of the Robustoïdes group proceeded normally in March. Harvesting of Liberia coffee began in the second half of the month.

*Tanganyika:* It was reported in March that, provided normal rains continued, the prospects for arabica coffee in the Northern and Southern Highlands Provinces and for robusta in Bukoba might be regarded as being good.

### Groundnuts.

*Argentina:* Except in Córdoba and Corrientes, the production of groundnuts this season is satisfactory in all the producing centres. The crop is of good quality.

*Netherlands Indies:* Java and Madura. — The Department of Agricultural Statistics With the Central Statistical Office communicates the following details of the groundnut area:—

	1939 acres	1938 acres
Area harvested in March . . . . .	50,400	61,000
Area harvested from January 1 to March 31 ..	134,700	140,600
Area of standing crops at the end of March ..	146,800	164,100

*Indochina:* Condition of groundnuts was good in Tonkin in March. Harvesting began in South Annam, Cambodia and Cochinchina; yields are very uneven, being in most cases mediocre owing to the drought.

*Tanganyika:* It was reported in March that groundnut production was expected to be below normal owing to diseases and scarcity of seed.

### Colza and Sesame.

*Germany:* On May 1 the crop condition of winter colza was 3.3 against 3.4 on April 1, 1939 and 2.7 on May 1, 1938. The corresponding figures for winter rape were 3.4, 3.6 and 2.6.

*Bulgaria:* The area under colza in 1939 is estimated at 57,800 acres against 50,900 acres in 1938 and an average of 22,000 acres in 1933 to 1937; percentages, 113.6 and 262.3.

*Netherlands:* Only 80 per cent. of the colza crops survived the exceptional rigours of the winter and the surviving crops were in poor condition. Crop condition, in the system of the country was 35 on April 17, 1939 against 73 on April 19, 1938.

*Poland:* In various districts colza, having been damaged by the December frost, was ploughed in. The crop is better only in certain parts of the south. On April 15 condition of winter colza was 2.9 as on March 15 against 3.5 on April 15 last year.

## Supplementary production figures.

As the 1938 or 1938-39 figure of production and area for most countries were published in the March number of the Monthly Crop Report and Agricultural Statistics, it is not necessary to repeat them again this month. Hence only new data and any modifications of the figures published last month are given in continuation. In another table is shown the total world production based on the figures received up to the time of going to press.

## Totals of World Agricultural Production.

The following totals have been obtained from the data in the tables published for each product in March, which have been revised and completed. With the name of each product is indicated the number of countries for which data for 1938 are at present available and also the percentage of the average world production in 1932 to 1936 as shown in the *International Yearbook of Agricultural Statistics 1938-39* (in the press) in which nearly all producing countries appear.

CROP (not including U. S. S. R. and China 1)	AREA					PRODUCTION							
	1938 — 1938-39	1937 — 1937-38	Average 1932 to 1936 1932-33 to 1936-37	% 1938 — 1938-39		1938 — 1938-39	1937 — 1937-38	Average 1932 to 1936 1932-33 to 1936-37	1938 — 1938-39	1937 — 1937-38	Average 1932 to 1936 1932-33 to 1936-37	% 1938 — 1938-39	
				1937 — 1937-38 1937-38 to 1938-39 = 100	Aver- age 1938-39 = 100							1937 — 1937-38 1937-38 to 1938-39 = 100	Aver- age 1938-39 = 100

### Current information on Fodder Crops.

*Germany:* On May 1, 1939 the crop condition of clover was 3.1 against 3.1 on April 1, 1939 and 2.7 on May 1, 1938. Corresponding figures for alfalfa were 2.7, 2.9 and 2.7; for irrigated meadows 2.5, 2.8 and 2.8; for unirrigated meadows 2.8, 3.0 and 3.0; and for pastures 3.0, 3.0 and 3.1.

*Belgium:* Many meadows after some weeks of grazing no longer provide feed for stock. Clover and rye-grass are in mediocre condition.

The data of production of fodder crops in 1938 compared with the figures for 1937 and the average for the preceding five years are as follows (in thousands):—

		1938	1937	Average 1932-1936	% 1938 1937 = 100	Average = 100
Mangels . . . . .	(centals)	101,331	124,034	127,233	81.7	79.6

(1) Green feed. — (2) Hay.

*France:* At the end of April the growth of meadows and pastures was satisfactory. Though rather retarded by cold weather at the end of the month, grass was sufficiently abundant to permit the grazing of stock. On the higher mountains, however, snow falls at the end of April prevented the use of high pastures. The first half of May was generally cold and wet and does not seem to have favoured growth. In certain localities meadows were flooded.

*Italy:* In the first half of April the growth of meadows and pastures was rather good, but in a number of districts was retarded by lack of moisture. In the second half of the month growth of meadows was retarded by drought and low temperatures.

*Latvia:* At the beginning of May the crop condition of annual clover was average in 36.7 per cent. of reports of correspondants, above average in 46.1 per cent. and below average in 17.2 per cent. Corresponding figures for perennial clover were 42.0, 24.3 and 33.7 per cent.

Limited quantities of ordinary fodder of generally below average quality were available, but supplies of concentrated feed were ample and of satisfactory quality.

*Lithuania:* The cool weather of April was not very favourable for meadows and pastures, and clover crops were late in beginning to turn green.

*Netherlands:* The intense cold of the beginning of the year greatly affected permanent meadows, clover and alfalfa, the growth of which is accordingly retarded. However, the fine weather of the second half of April somewhat improved the condition of permanent meadows. Red clover has practically failed, while alfalfa has been a little less affected by the frost. These poor conditions are reflected in the following table of crop condition, expressed in the system of the country:

	April 17 1939	April 19 1938
Permanent meadows. . . . .	54	74
Clover . . . . .	40	73
Alfalfa . . . . .	54	67

*Poland:* In several areas clover, having been damaged by the December frost, was ploughed in. The crop is better only in the Lublin area. On April 15 condition of clover was 2.9 as on March 15 against 3.2 on April 15 of last year.

*Switzerland:* The wet weather of April greatly stimulated the growth of permanent and rotation meadows, which have a thick sward and abundant growth. Conditions are in contrast to last year when growth was retarded by drought. It seems safe to count on a quantitatively good crop of hay. Crop condition on May 1, 1939, in the system of the country, was 82 for permanent meadows (against 81 on April 1, 1939 and 53 on May 1, 1938); that of rotation meadows was 84 against 81 and 56 respectively.

*United Kingdom:* Pastures were backward at the end of April especially on high, exposed ground. Growth was general in the second week of April but was subsequently checked again by a return of cold and windy weather and by grazing.

*Argentina:* The condition of pastures in April was generally good.

*Canada:* The condition of hay and clover meadows on April 30, 1939 was 97 compared with 100 at the same date last year.

*French Morocco:* The weather in April was changeable with frequent variations in temperature and direction of wind; rains were of short duration but widespread. Cisterns are full and subterranean and surface water reserves are abundant. The bite on grazings on the plains is substantial, but on the mountains is insufficient owing to cold spells in April having checked growth.

*Australia:* Pastures in the south coastal districts of New South Wales made rapid growth following excellent rains during March and heavy rain also in the north coastal areas assisted growth. Except in the central tablelands and parts of the central western slopes of the State prospects for stock were considerably improved by the rain. The period of butter production was likely to be prolonged.

Excellent rains throughout Queensland greatly improved pastures and dairy production soon showed a marked increase. Ample green feed and water seemed to be assured for some time.

Moderate to heavy rains fell over the greater part of South Australia in March. There was an abundance of feed and water in pastoral districts at the beginning of April.

In Western Australia March was hot and dry but, following the heavy rains of January and February grasses were holding well on the south coast and conditions were variable

## LIVESTOCK AND DERIVATIVES

### Livestock in Albania.

The following table shows the number of the different classes of livestock at the end of 1938 with corresponding figures for 1932 to 1936. No statistics are available for 1937.

CLASSIFICATION	1938	1936	1935	1934	1933	1932
<i>Horses</i> . . . . .	54,426	67,791	67,154	68,240	66,750	62,490
Geldings . . . . .	28,587	34,288	34,200	34,985	34,915	32,500
Mares . . . . .	25,839	33,503	32,954	33,255	31,835	29,990

### Wool Production in Canada.

Shorn wool production in Canada in 1938 is estimated to have amounted to 13,386,000 lb and that of pulled wool to 4,309,000 lb. The total—17,695,000 lb.—compares with 17,629,000 lb. in 1937 and 17,431,000 lb. in 1936. The average yield per sheep of shorn wool was 7.3, 7.2 and 7.2 lb. respectively while the average yield of pulled wool is assumed to have been 3.5 lb.

### World Trade and Prices of Cheese in 1938.

Cheese is not, as is butter, a uniform dairy product distinguished only by different qualities. The word "cheese" is rather a comprehensive term covering a very large number of products more or less distinct from each other. These differences arise from variations in the origin and fat-content of the raw material, in the process of manufacture and in the consistency and conservability of the product. However, in reviewing the international trade situation it is necessary to ignore the different types of cheese, not only for the interest of considering the cheese trade as a whole, but also because the statistical data available do not allow any other course to be taken.

The aggregate volume of world trade in cheese reached its peak, for the post-war period, in the year 1930, with total exports of 768,093,000 lb. In 1936 the amount had fallen to 593,222,000 lb. The increase, which took place in 1937, was continued in 1938 but only to a very small degree.

The number of large cheese exporting countries is much smaller than in the case of butter. Nine countries together contribute about 90 per cent. of

world exports. The aggregate exports of these countries increased by only about 6,610,000 lb. between 1937 and 1938 against a rise of 37,500,000 lb. between 1936 and 1937. In fact, in the case of the three largest exporting countries, New Zealand, Netherlands and Canada there was even an appreciable fall in 1938. New Zealand

The foreign trade situation of the United Kingdom, which is the largest cheese importing country, is given in a special table. It is to be regretted that the classification by countries of origin does not also include a classification by types of cheese, but no information is available in this respect. Nor do statistics of the supplying countries give much information on this point. The only comment that can be made is that the changes in United Kingdom imports between 1937 and 1938 correspond roughly with the fluctuations in the total exports of the countries of provenance.

A number of countries, including France, Italy and Switzerland, are both importers and exporters, the explanation being that the cheeses entering into international trade are of different qualities.

A differentiation by kinds of cheese is not made in statistical returns or, except for the United States, is only done in a very general way by groups. Classification into hard cheese and soft cheese is quite common and is sometimes supplemented by a sub-division for semi-hard cheese. Although

such a classification is very arbitrary and uneven—e. g., in France Gorgonzola is considered a hard cheese and in Italy a soft cheese—it assists the interpretation of international trade.

(1) Not including processed cheese in boxes or in blocks.

The statistics of French exports separate trade with the colonies from that with foreign countries. They indicate that the colonies take most of the hard cheese. Semi-hard exports to the colonies in 1938 were about the same as in the previous year while exports to foreign countries were greater. Most of the soft cheese trade is with foreign countries, mainly owing to the considerable demand of the United States for Roquefort cheese. The proportion of hard cheese in Italian exports is greater than in those from France. Direct comparison between the two countries, however, is difficult owing to the differences in statistical recording.

Statistics of imports show more clearly than those of exports that hard cheese predominates in international trade. Thus, German imports, which in 1938 amounted to 71,675,000 lb., comprised only 1,500,000 lb. of soft cheese.

The fact that the cheese trade between the European exporting countries reaches such a high level is to be attributed mainly to the great variety of products included under the general heading of cheese. Many of the different kinds of cheese are still made in their places of origin despite technical progress and modern methods. Clear evidence of this can be seen, thanks to classification by variety, in the trade statistics of the United States. These statistics, which are not yet complete for 1938, illustrate the dominant position held by some exporting countries for certain kinds of cheese.

The prices of cheese expressed in gold francs are mainly intended to illustrate the course of prices of each kind and on each market considered. They

after 1930, the lowest levels being touched in 1934 and 1935. The rise in subsequent years was interrupted in some cases in 1937. In 1938 prices recovered nearly everywhere with the rise in general price levels.

W. SCHUBRING.

### Current information on Livestock and Derivatives.

*France:* At the close of the winter the condition of stock was rather mediocre owing to under-nourishment and the effects of foot-and-mouth disease. Farmers' stocks of hay were practically exhausted at the end of April. But the growth of grass promised a rapid improvement and an increase in milk production was already to be noted. The first half of May, however, was cold and wet and seems to have been unfavourable for stock in general.

*Ireland:* Weather conditions in April were cold and harsh with the result that the demand on limited supplies of fodder was unusually heavy. Supplies of last year's fodder were running low but the season for grass is at hand and no serious trouble was anticipated. There was a marked decrease in milk yields owing to the lateness of grass and the scarcity of hay.

*Italy:* According to a study recently made by the Central Statistical Institute, the production of cows' milk in Italy in 1938 is estimated at 1,512,440,000 Imperial gallons (1,816,300,000 American gallons), of which 80.4 per cent. is produced in Northern Italy, 10.6 per cent. in Central Italy, 5.6 per cent. in Southern Italy and 3.4 per cent. in the Islands. The utilization of milk is approximately as follows 22.2 per cent. for feeding to calves, 34.0 per cent. for manufacture and 43.8 per cent. for liquid consumption. The number of cows on March 19, 1938 was estimated at about 3,800,000, of which 72.8 per cent. were in Northern Italy, 15.4 per cent. in Central Italy, 7.5 per cent. in Southern Italy and 4.3 per cent. in the Islands.

*Latvia:* Milk production in April this year was 5 to 7 per cent. higher than in April 1938.

*Netherlands:* Feeding conditions for milk cows were good during March in all parts. Milk production was 3 per cent. larger than in the same month of 1938. In Utrecht, Zeeland and North Brabant production hardly differed from normal. In South Holland it declined by about 2 per cent. It increased by 2.5 per cent. in North Holland, 4 to 5 per cent. in Friesland, Drente and Limburg, and 7.5 per cent. in Groningen, Overijssel and Gelderland.

*United Kingdom:* Milk yields were difficult to maintain in April despite continued artificial feeding.

*Switzerland:* Deliveries of milk in January were 1.8 per cent. less and in February 1.5 per cent. less than in the corresponding months of 1938. The drop in production was particularly heavy in areas seriously affected by epizootis, while in other parts of the country, particularly Western Switzerland, there was a slight increase. With the falling off of the epizootis epidemic, milk production increased again so that in March, deliveries were slightly higher in the country as a whole than last year.

*Argentina:* The condition of stock in April was good except in Patagonia and the west of the grain belt.

*United States:* The number of cattle on feed for market in the 11 Maize Belt States on April 1 was estimated by the Bureau of Agricultural Economics to have been about 13 per cent. larger than a year earlier. This increase was equivalent to about 160,000 head. Though this increase follows an increase of 20 per cent. last year, the number on feed in early April this year was not yet back to the number on the corresponding date in most of the 15 years prior to 1934. The States in the

Western Maize Belt showed the largest increases but the numbers there were still considerably below the pre-drought. Moderate increases in the Eastern Maize Belt States brought the numbers on feed to the highest level for the past 10 years.

Development of the early lamb crop during March was below average for the country as a whole and much below the exceptionally favourable development in March 1938. Mild temperatures during much of March in all important early lambing States were favourable for the growth of the early lambs but the shortage of green feed in California and Texas, resulting from deficient moisture, and too many rainy and cloudy days in some of the other States more than offset the favourable effects of the mild temperatures.

With rather general rains and cool weather during March, feed conditions in California improved somewhat but range and pasture conditions on April 1 were still much below average. Slaughter lambs were expected to be below average in weight and finish. A continuation of poor feed conditions in Texas tended further to retard the development of both early and yearling lambs. Lambings in southeastern early lamb States were below average. Green feed was somewhat short because of the poor condition of grain pastures and the slow start of other pastures.

*Union of South Africa:* Good rains fell in March in most parts of Cape Province, except in the north-east. Grazing generally was abundant and prospects for stock for the coming winter were favourable. In Natal, Transvaal and the Orange Free State there was little rain in March, but following the heavy rains of February grazing was still very good. Stock generally were in good condition.

### Current information on Sericulture.

*France:* Incubations this year are very much smaller.

*Indochina:* Mulberry bushes were growing again in March in North Annam. In Central Annam, they suffered considerably from drought but the situation was remedied partly by rains at the end of the month.

*Japan:* The quantity of silkworm eggs placed in incubation for spring cocoons is estimated at 2,025,900 ounces against 2,068,600 ounces in 1938 and an average of 2,535,500 ounces in 1933 to 1937; percentages, 97.9 and 79.9.

## VARIATIONS IN THE INDEX-NUMBERS OF PRICES

The index-numbers of prices of agricultural and other products of interest to the farmer, as published by the various countries, are often very heterogeneous and consequently great care has to be taken in drawing conclusions from the supplementary information given in the following comparative summary table.

COUNTRIES	Percentage variations in the index-numbers of prices of			
	agricultural products	all products	agricultural products	all products
	April 1939 in comparison with			
	March 1939		April 1938	
Germany (products sold by farmers) . . . .	+	1.0		0.0
Germany (wholesale prices) . . . . .	—	0.5	—	—
England and Wales (a) . . . . .		0.0	+	1.5
England and Wales (b) . . . . .		0.0	+	2.3
Argentina . . . . .	+	4.4	+	2.2
Australia . . . . .	—	3.0	—	20.9
Canada . . . . .	—	2.6	—	1.9

(a) Wool, greasy. — (b) Wool, scoured.

(x) For 1939 the figures refer to Bohemia and Moravia and cover the period March 16 to April 30.

## PRODUCTION

*Algeria:* Rain in April was very heavy and caused some flooding.

Among cereal crops is reported a first appearance of rust in the littoral and sub-littoral on leaves and ears, particularly on early soft wheat. Some damage was also done in Oran by white worms. Nevertheless, crops are reported to be good on the whole, particularly barley. The following figures are the provisional crop forecasts made in April compared with the final results of preceding years. The realization of these approximate forecasts was dependent on an improvement of weather conditions in May.

### *Production of Cereals.*

	(1) 1939	1938	Average 1933-37	1939	1938	Average 1933-37	% 1939 1938      Average = 100    = 100	
	(ooo centals)			(ooo bushels)				
Hard wheat . . . . .	18,629	13,744	13,945	31,048	22,905	23,242	135	134
Soft wheat . . . . .	8,267	7,115	6,700	13,779	11,859	11,166	116	123
<i>Total wheat . . . . .</i>	<i>26,896</i>	<i>20,859</i>	<i>20,645</i>	<i>44,827</i>	<i>34,765</i>	<i>34,408</i>	<i>129</i>	<i>130</i>
Rye . . . . .	25	25	18	44	44	31	100	140
Barley . . . . .	22,046	12,791	16,389	45,931	26,648	34,143	172	134
Oats . . . . .	3,968	3,486	3,234	12,401	10,892	10,107	114	123

(1) May 1 forecasts.

Among vines the growth of clusters was satisfactory. Mildew is reported locally and if the moist weather continues a severe attack is feared.

The blossoming of olives was very abundant but took place in bad conditions and shedding was feared. If weather conditions should improve a good crop was anticipated.

*Germany:* The area re-ploughed owing to winter and other damage in 1939 was for winter rye 89,000 acres, or 9.0 per cent. of the sown area, against 16,300 or 0.1 per cent., in 1938, and an average of 110,100, or 1.0 per cent. in 1931-1936; for winter wheat corresponding figures are 371,000, or 8.0 per cent., against 9,800, or 0.2 per cent., and an average of 97,600 or 2.2 per cent.; for winter barley 331,000 or 25.0 per cent., against 600, or 0.1 per cent. and 9,200 or 4 per cent.; for clover mixtures 293,000, or 8.0 per cent., against 17,100, or 0.5 per cent. and 99,600 or 2.2 per cent.; alfalfa 25,000, or 2.5 per cent., against 2,300, or 0.3 per cent. and 18,700 or 2.5 per cent.

*Hungary:* The last decade of April was dry and cool, while the first decade of May was wet and warm. Precipitation was above average. Weather conditions on the whole were favourable for crops.

On May 10 the crop condition of winter wheat was good in most parts, while that of winter rye varied from average to good. Winter barley had a good appearance at this date. Spring cereal sowings were slightly affected by drought in April but following the rains in May were growing rapidly.

On May 10 the sowing of maize was finished. Early sown crops rose well and the first hoeing was in progress. Rain in May considerably stimulated late sown crops.

The planting of potatoes on May 10 was finished. Early potatoes sprouted well and were growing strongly following the rains in May. The first hoeing was in progress in nearly all districts. At the same date main season potatoes were beginning to grow or were in process of germination.

The condition of vines is satisfactory on the whole. The damage done by spring frost is slight.

Mangels did not germinate evenly. Following the rain, clover and alfalfa were growing very rapidly. The first cutting was in progress and yields were above normal. Vetch and rye mixtures for fodder were growing well on May 10. The sowing of maize for fodder and of mohar was in progress. The growth of permanent meadows and pastures was vigorous following the rain.

*Portugal:* The condition of cereals improved considerably as a result of rain in the second half of April and, although there have been complaints of frosts in a number of areas, the crop will be good if the east winds which normally blow at this period do not damage the plants. Spring seeding was generally finished in good conditions.

Frost slightly damaged vines.

Fodder crops have not been much affected by the variable weather of April and crops are considered fairly abundant.

*Romania: Cereals.* — On May 20 wheat and cereals generally were growing normally. *Maize.* — Sowing of maize was finished in good conditions. The weather is favourable for growth.

## VEGETAL PRODUCTION

### The World Wheat Trade in 1938-39 and 1939 Wheat Crop Prospects.

International trade in wheat during April 1939, the latest month for which official statistics of exports and imports are available, showed the usual seasonal decline compared with the first quarter of the year. This year, however, the decline in world exports in April has been much less marked than usual, first because the export of the Argentine crop, which had been extremely small in January to March, rose sharply in April, and secondly because the Danube countries, especially Hungary and Romania, in April accelerated the disposal of their exportable supplies after a diminution in March.

From August to April, or during three quarters of the present season, world net exports totalled 447 million bushels, an increase of 42 millions, or 10 per cent, on last year. Last March we forecast world import requirements of the whole season at 570 million bushels; the actual exports of the first nine months of the present season give reason to believe that this forecast will be practically realized. The considerable drop in wheat prices in the spring, by stimulating demand and facilitating the building up of reserve stocks, will enable exports to be maintained at a higher level than usual and to remain in the last few months of the season at the level of the preceding months, instead of the usual seasonal decline towards the end of the season. In that case the total of world exports in 1938-39 might exceed by 15-20 million bushels our March forecast.

\* Aggregate net exports of the normal exporting countries (possible net imports into certain of these countries are not deducted from the totals).

(1) Forecast March 1939. — (2) Net exports adjusted in accordance with the monthly variations in stocks of Canadian wheat in the United States and stocks of United States wheat in Canada. — (3) Bulgaria, Lithuania, Poland and Yugoslavia. — (4) Iran, Iraq, Turkey, Chile and Uruguay. — (5) Net imports.

The estimates of the exportable supplies of the various exporting countries have not undergone any modification worth noting and their total for the present season remains the same as that published last month. Deducting from these surpluses the export figures of August to April, the remaining exportable surplus on May 1, 1939 in exporting countries amounted to about 700 million bushels, which is an extremely high total and well over double the amount on May 1, 1938. It is thus confirmed that the stocks of exporting countries to be carried over to the 1939-40 season will be very heavy and will approach, though not fully reach, the maximums of the period 1929 to 1934.

On May 1 about a half of the exportable balance was centred in North America (United States 32 per cent. and Canada 18 per cent.), 27 per cent. in Argentina, 13 per cent. in the Danube countries, 8 per cent. in Australia and the remainder in the other minor exporting countries. In all the chief exporting countries except Australia supplies on May 1, 1939 were much larger than on May 1, 1938. Surplus stocks in Argentina and in the Danube group of exporting countries were exceptionally large.

In regard to the importing countries the net wheat imports of Europe showed a heavy fall in April compared with the average monthly imports of this season

(1) Forecast March 1939. — (2) After deduction of net exports of 1 million bushels from Sweden and of 1 million bushels of net exports from Czecho-Slovakia. — (3) After deduction of net exports of 0.7 million bushels from Sweden. — (4) After deduction of net exports of 6 million bushels from Czecho-Slovakia. — (5) After deduction of net exports of 9 million bushels from Czecho-Slovakia. — (6) Denmark, Estonia, Finland, Latvia, Norway and Sweden. — (7) Czecho-Slovakia, Spain, Portugal, Albania, Malta, etc. — (8) Total after deduction of net exports.

and with April 1938. This sharp drop was due essentially to the United Kingdom, which only imported 12 million bushels in April 1939 against 26 millions the previous month and 14 millions in April 1938.

Ireland, however, showed a considerable increase in imports in April with 2.5 million bushels against an average of 1.3 millions in the preceding eight months. The aggregate imports of the British Isles from August to April show an increase of 23 million bushels on the corresponding period of the preceding season. On the other hand, the Continental countries imported on the whole 5 million bushels less than last year. For Europe as a whole we have forecast for the whole season requirements of 430 million bushels, of which only 310 millions have already been imported in the first nine months. The imports of the last three months would therefore have to average 40 million bushels, a considerable increase on the 34 millions imported monthly from August to April. In view of the heavy shipments to Europe in May and the first half of June there is reason to believe that the imports of the last quarter will be very close to the high level anticipated.

The imports of the extra-European countries continued at a very much higher level than last year owing to the heavy demand of the Far Eastern countries and of Central and South America.

### 1939 Crop Prospects.

From reports received by the Institute up to June 20, the following indications of wheat crop prospects in the Northern Hemisphere may be given.

In Europe the weather was very variable in May in different parts of the continent. In the north it was mostly fairly sunny and warm; in the centre it was irregular with sudden changes of temperature; and in southern Europe it was abnormally cold, wet and stormy. On the whole during May crop condition mostly improved very slightly in the north and centre and deteriorated fairly considerably in the south, where, however, crops were still more or less satisfactory, in spite of the damage done by excessive rain and frequent, severe storms.

In the first half of June the weather was more favourable in almost all parts. Although there was frequent rain with occasional storms, seasonal conditions became more normal with fine, sunny days and a steadily rising temperature. There was no excessive heat or waves of scirocco, which in the Mediterranean region might have done serious damage owing to the general lateness of growth after an abnormally cold May. The absence of great heat also checked the spread of rust, which made an appearance in many districts following the excessively wet May and early June in Italy and in the Danube and Balkan countries. Owing to the lateness of crops after the cold spring, the harvest will begin one or two weeks late in most of the countries which normally begin harvesting in June. At mid-June crop condition generally was fairly considerably better than at the beginning of the month. Crop prospects, in spite of the great uncertainty caused by the lateness of crops, seem to indicate a more or less average outturn for the continent as a whole.

For a number of years we have attempted at this time of year to give a numerical forecast of the European wheat crop, on the basis of the areas under cultivation in the different countries and the probable unit-yields as indicated by crop condition, assuming, of course, that weather conditions between mid-June and the end of the harvest are normal. Clearly, such a forecast may be very far from the actual results, due not only to errors of judgment on the actual condition of crops but also to weather conditions in the coming weeks, which may have a decisive influence on the size of the crop. We believe, however, that such a forecast may be useful. It gives a first indication of the world wheat market situation in the coming 1939-40 season. We publish it below with due reserve and may revise the figures next month, when crop prospects are more definite. The forecast puts the production of the importing countries of Europe at 1,140 million bushels and that of the six exporting countries (four Danube countries, Poland and Lithuania) at 500 millions, giving a total crop for Europe as a whole (excluding the U. S. S. R.) of 1,640 million bushels.

*European Wheat Production Estimates.*

(million bushels)

Years	Importing countries	Four Danube countries, Poland and Lithuania	Total Europe
1939 (forecast) . . . . .	1,140	500	1,640
1938 (final) . . . . .	1,288	553	1,841
1937 " . . . . .	1,109	440	1,550
1936 " . . . . .	1,010	471	1,481
1935 " . . . . .	1,189	386	1,575
1934 " . . . . .	1,212	330	1,548
1933 " . . . . .	1,289	456	1,745
1933-1937 (average) . . . . .	1,162	418	1,580
1928-1932 " . . . . .	1,030	399	1,429
1923-1927 " . . . . .	921	323	1,244

According to this forecast, the 1939 wheat crop in Europe as a whole would be definitely (about 11 per cent.) smaller than the exceptionally large crop of last year but would still be one of the largest crops of post-War years, being in fact only exceeded by those of 1933 and 1938. The position of the crop, however, is rather different according to the separate groups of importing and exporting countries. It is found that the aggregate production of the former would be about average (1,140 million bushels against an average of 1,160 millions in 1933 to 1937) while that of the six exporting countries would be extremely large and well above the previous five-year average (500 million bushels against 420 millions in 1933-1937).

In the Soviet Union, weather conditions in May and the first half of June were on the whole favourable. The rainfall of the second half of the spring was on the whole abundant and fairly well distributed. This rainfall is of importance both for winter cereals, which are already approaching maturation, and for the

growth of spring cereals, the late sowings of which were completed at the beginning of June. In some parts of the southeast and particularly in the Volga basin drought persisted in May and the light, scattered rain that fell in the first half of June was not sufficient for the growth of crops which were in great need of heavy rain. At mid-June winter wheat and rye which had not been affected by the winter and spring frosts had a good appearance and promised good yields particularly in Ukraina and in North Caucasus. Spring wheat production, which constitutes nearly two-thirds of the total wheat crop of the Union, still remains entirely dependent on weather conditions and particularly the rainfall from mid-June to mid-July, which is the most important factor in determining good crops. An important fact to note is that on June 10 soil moisture reserves were still considerable. On the whole, prospects at present are for a large crop. The fact that on the London market offers of new crop Soviet wheat are beginning to be made seems to confirm the optimism which prevails in regard to the coming harvest.

In North America, winter wheat crop prospects in the United States slightly fell off during May and the June 1 estimate showed a decrease of about 4 per cent. compared with the preceding month. The forecast production of 523 million bushels is much lower (24 per cent.) than the excellent crop of last year and is only slightly (5 per cent.) above the low average of the five preceding years. The weather of the first three weeks of June was favourable for the maturation of winter wheat and harvesting has already begun in some districts although it was interrupted in some cases by rain. Some attacks of rust are reported, but it does not seem that any serious damage has been done so far. It is anticipated that the July 1 estimate will show a fairly considerable advance on the June 1 figure. Spring wheat, the crop condition of which was not satisfactory on June 1 owing to drought in May, benefited in the first three weeks of June from frequent and widespread rains in the principal producing areas. Crop condition has greatly improved and prospects are satisfactory. If damage in the later stages does not overthrow present expectations, the aggregate wheat production of 1939 should be largely sufficient to supply the internal requirements of the United States.

The first stages of growth of spring wheat in Canada were hampered by the drought of the first two decades of May and crops only began to improve from the third decade on with the arrival of general rains in the Prairie Provinces. Wheat crop condition on June 1, though satisfactory, was not so good as a year earlier. In the first three weeks of June the season was definitely favourable, with rather low temperatures and heavy, frequent and widespread rain. Crops made excellent progress and were only in need of a slight rise in temperature and more sunshine. If there is further occasional rain in July and if the still very doubtful menaces of rust and grasshoppers are not realized, Canada may expect a definitely good crop, clearly exceeding the already large crop of last year, which reached 350 million bushels.

In regard to Asia, we have already published last month the second estimate of production in India, which is large. Chosen and Palestine this month sent their crop estimates, which in both cases are very high. In Japan the condition of

crops, following favourable weather, promises high yields. In the Near East, crop prospects are good both in Turkey and in Syria.

In North Africa, the provisional estimates of the three countries of the French zone indicate a total production of 102 million bushels, an increase of about 40 per cent. both on last year and the five-year average. These three countries also anticipate an exceptionally large barley crop. In Egypt harvesting is nearly completed and results are very satisfactory.

Summarizing reports at mid-June on the probable wheat crop in the Northern Hemisphere, it may be said that wheat production in 1939 is definitely smaller than the large crop of 1938 but is well above the average of 1933 to 1937. If crops maintain their present promise the total production of the Northern Hemisphere (excluding the U. S. S. R. and China) may reach 3,530 million bushels, or about 10 per cent. less than last year, but still 11 per cent. more than the average of 1933 to 1937.

In regard to sowings in the Southern Hemisphere, it is confirmed that seeding in Argentina, somewhat delayed by drought in some areas, progressed in favourable soil and weather conditions in June. The situation is also favourable in Australia, where rain this month has been frequent and general, ensuring a good germination. A slight reduction in the sown area both in Argentina and in Australia is anticipated.

G. CAPONE.

### Current information from various countries on Wheat, Rye, Barley and Oats.

#### Europe.

*Germany:* The crop condition of cereals was good on the whole at the beginning of June, except for winter barley, which was damaged during the winter. Spring cereals were also in fairly good condition.

*Belgium:* The weather in the second half of May was fine and dry. Drying winds from the northeast and east did some harm. Crop condition is generally good; winter wheat, resown in February, is naturally rather retarded. Spring cereals are in good condition.

According to the most recent estimate the area cultivated to spelt this year is about 23,100 acres against 24,500 in 1938 and 32,100 on the average of the five years ending 1937; percentages 96.6 and 72.1.

*Bohemia-Moravia (Protectorate).* — Except in the second half of December, when the temperature fell to 4° below zero F., the winter was generally mild and dry. In March there was cold, wet weather and in April mild and comparatively dry weather. Spring cereals, the sowing of which had been retarded by the cold, wet weather of March, improved during the mild weather of April, and on May 1 crop condition was good.

Winter cereals were considerably damaged in some areas, especially late-sown crops, and in some districts they have been replaced by other crops. Thanks, however, to the fine weather of April, the crop condition of winter cereals improved considerably and at the beginning of May was good.

*Bulgaria:* The weather in May was fine on the whole and rather wet. The average temperature was normal. As a result of the rain and adequate warmth winter

crops were of very good appearance at the beginning of June. The sowing of spring cereals was carried out in very favourable conditions.

The preliminary estimates of the General Statistical Department of Bulgaria for the 1939 crop of winter cereals compared with that of 1938 and the average of the years 1933 to 1937 are as follows:—

	1939	1938	Average 1933-1937	% 1939 1938 = 100	Average = 100
	(thousand centals)

(1) Year 1937.

*France:* The first two decades of May were cold and particularly wet, with almost daily rainfall. In the last decade the temperature was high with a stormy sky and a strong north wind, which dried the ground excessively.

The condition of winter wheat is definitely not so good as at the end of April. Weeds have developed very rapidly while wheat has been retarded in growth by the cold weather. Rain has not enabled hoeing and weed-killing to be carried out successfully. Moreover rain encouraged the spread of rust, which is reported in all low-lying and clayey lands. In regard to alternative or spring wheat, crops may be divided into two categories: wheat sown in January is vigorous and fairly dense and clean; that sown later after the second period of frost is thin and weed infested.

Rye has a very satisfactory appearance. Flowering and fructification took place in good conditions. Oats and barley germinated well but are infested by weeds. It is reported that the area sown to barley is rather higher than the average of previous years, since many farmers have turned over their wheat fields destroyed by the frost to this crop.

*Finland:* The temperature in May was considerably higher than normal. There was little precipitation during the month, and the rain that fell was very unevenly distributed. Crops came through the winter in poor condition. Spring sowing took place in normal conditions.

*Greece:* After a rather long period of fine and dry weather, rain at the end of May and in the first ten days of June damaged cereals particularly on the plains, causing lodging or interrupting the harvest, which had begun. In mountain districts the wet weather rather favoured the growth of cereals. At the end of the first decade of June, when the fine weather returned, the condition of cereals was as follows. In Central Macedonia, Epirus and Thessaly, in spite of rather serious damage done by the bad weather, a larger crop of cereals than last year is forecast. In Thrace and the Peloponnesus production is reported to be about equal to last years'. In Euboea, Crete and the islands of the Aegean, particularly Lesbos, the production of cereals is forecast as generally lower than last year.

On the whole, on June 10 there was good reason to believe that the crop was not yet seriously damaged, but a continuation of the rains or a sudden rise in temperature might well affect cereal production unfavourably, though for the moment the crop is considered satisfactory.

*Hungary:* Wet weather and rather low temperatures continued in the last week of May and the first week of June, while the second week of June was warm and sunny. At the middle of June early sown crops of all cereals were dense and of very good appearance and the ears were well developed; only in the case of rye did the situation appear rather less favourable, as a result of the weather conditions which in many districts were unsatisfactory for flowering. Late crops were on the whole rather thin, with ears still undeveloped. On the whole it was possible to forecast a good or good average crop of wheat and good to average crops of rye, barley and oats.

(Telegram of June 26): The first estimates of cereals area and production in 1939, as compared with the final figures for 1938 and the of average 1933 to 1937, are as follows:—

CROPS	AREA					PRODUCTION					
	1939	1938	Aver- age 1933-37	% 1939		1939	1938	Aver- age 1933-37	% 1939		
				1938 = 100	Aver- age = 100				1938 = 100	Aver- age = 100

						th. centals	20,084	17,739	16,030	113.2	125.3
						th. bushels	35,865	31,677	28,625		

*Ireland:* May was exceptionally dry with very low night temperatures for the greater part of the month. Cereal crops progressed fairly satisfactorily, but rain was badly needed towards the end of the month.

*Italy:* In the first half of May the weather was on the whole wet and the temperature rather low. Storms, hail and strong winds were frequent. At the middle of the month the condition of wheat and other winter cereals, in spite of the unfavourable conditions, was on the whole still good or satisfactory. Persistent rain and winds in the second half of the month damaged crops and encouraged the spread of rust. However, on the whole, crop forecasts at the end of the month were still good.

*Latvia:* In May the weather was dry and windy and the temperature on the average 3° F. below normal. It was rather cold in the first half of the month and there were frequent night frosts. At the beginning of the second fortnight the temperature rose a little above normal but fell again sharply towards the end of the month. In the first fortnight the weather was very dry, and rain only fell in small quantities towards the end of the month. According to the reports of agricultural correspondants, the crop condition of wheat at mid-May was average in 52.6 per cent, of farms, above average in 13.9 per cent. and below average in 33.5 per cent. The corresponding figures for winter rye are 57.7 per cent, 27.4 per cent and 14.9 per cent.

*Lithuania:* May was dry and rather cold. There was even hoar-frost towards the end of the month. These conditions were very favourable for field work. The sowing of spring cereals proceeded actively in the first two decades of the month, and by May 20 was approaching completion. Owing to cold weather, growth is only making slow progress. Early sown cereals have risen well but the cold weather checked their growth. There were complaints of invasions of weeds.

*Luxemburg:* The cold, wet weather of the first half of May and the generally low temperatures throughout the month hampered the normal growth of all crops.

*Norway:* No winter damage is reported; following the cool weather of April and May the snow remained a long time in the north. At the end of May the preparation of the fields was completed. In the east rainfall was adequate, while in the west and south it was insufficient. For good growth crops are in need of further rain and high temperatures.

*Netherlands:* Weather in May, in the period preceding development, was not quite favourable. Precipitation was generally below normal and temperatures remained rather low. At the end of the month there was a complete change, with sunny dry weather until the middle of June. The effect on crops, which already required water was rather unfavourable.

Winter wheat showed very great differences: that sown early developed fairly well while that sown later was backward. On the whole crop condition in mid-June was almost good. Rye also suffered from drought and its growth was slow. Winter and spring barleys were in average condition. Spring wheat was generally better developed than winter wheat. In Zuid-Holland and Zeeland conditions were good to very good, in Groningen fairly good to good. On the sandy soils growth of winter wheat was less satisfactory. Condition of oats varied greatly according to quality but on the whole was fairly good.

*Poland:* According to the reports of the majority of crop correspondents, the weather in the second half of April was dry and sunny but rather cold, and in the north of the country there was even hoar-frost. Towards the end of April the weather turned warmer but only for a few days. At the beginning of May the temperature fell again and almost the whole of the month was rather cold with heavy

rainfall. Accordingly, 60 per cent. of correspondents reported for the second half of May insufficient warmth and sun and 50 per cent. also reported excessive soil moisture. A lack of warmth was recorded particularly in the south, except in the Tarnopol, Silesia, Kielce, Lodz and Poznan areas, where 60 to 100 per cent. of correspondents reported excessive soil moisture.

The heavy rain accelerated the growth of winter cereals, but caused lodging on low-lying land. Spring cereals have grown on the whole in good conditions.

In spite of the rather unfavourable weather in the period from May 15 to June 15, compared with the period April 15 to May 15, crops condition generally improved particularly for winter cereals, as is seen from the following table:

	June 15	1939	May 15	1938
		June 1		June 15
Winter wheat . . . . .	3.7	3.6	3.4	3.8
Winter rye . . . . .	3.7	3.6	3.4	3.7
Spring wheat . . . . .	3.2	3.3	3.1	3.3
Spring barley . . . . .	3.2	3.3	3.1	3.2
Oats . . . . .	3.2	3.3	3.1	3.1

Crop condition of cereals on June 1 was improved in the Wolhynia, Tarnopol and Lublin areas, but had deteriorated at Wilno and Nowogrodek.

*Romania:* On June 20 the crop condition of cereals was good. In the south and east the harvesting of winter wheat had begun. Production will be very satisfactory, although the crop has suffered from rainstorms and rust. Spring barley will give a good yield, much better than last year. The oats crop, on the other hand, is rather unsatisfactory.

The first estimates of cereals area and production in 1939, as compared with the final figures for 1938 and the average of 1933 to 1937, are as follows:

CROPS	AREA						PRODUCTION				
	1939	1938	Ave- rage 1933-37	% 1939			1939	1938	Ave- rage 1933-37	% 1939	
				1938 = 100	Ave- rage = 100					1938 = 100	Ave- rage = 100

						th. bu.hels	41,337	31,904	45,792		

*United Kingdom:* The areas sown to wheat, barley and oats in England and Wales show little change this year as compared with 1938.

Except for cold wet spells at the beginning and middle of the month, May was dry, sunny and warm. Conditions were favourable for agriculture, but rain was badly needed at the beginning of June. Winter wheat is generally strong and healthy.

Spring wheat germinated well but is still backward and patchy in some districts. Winter barley was not successful, but spring barley, though variable and slow in growth is promising. Oats generally look well, but some spring oats are backward.

*Switzerland:* Such a cold May has not been recorded since 1902. But, in spite of that, there were no destructive frosts. Cereal crops stood up fairly well to the bad weather. Lodging slightly damaged winter crops and the cold weather somewhat checked the growth of spring crops. On the average cereals are in better condition than at this period of last year. The crop condition of spelt at the beginning of June was, in the system of the country, 84 against 85 on May 1, 1939 and 82 on June 1, 1938.

*Sweden:* The winter was comparatively mild and crops on the whole came through well. In May growth was hampered by unfavourable weather conditions.

*Yugoslavia:* The dry weather of April and the first decade of May checked the growth of cereals, which remained thin and short in a number of districts. Heavy, stormy rain, particularly in the Banate of the Danube at Backa and Irem and less strong at Banat, at first brought about an appreciable improvement in cereal crops. But violent hailstorms occurred almost throughout the country at the beginning of the second decade of May, causing floods and consequently doing serious damage to cereal crops. The persistence of rain and the fall in temperature, lasting to the end of the first decade of June caused serious fears for crops. In fact, lodging and attacks of rust and ergot were reported in a number of districts. The return of fine, dry weather on about June 10 considerably improved crops, which, after being forecast on June 1 as poor and about 30-35 per cent. below last year's, are now considered satisfactory and only about 20 per cent. smaller.

*U. S. S. R.:* On May 31 the area sown to all spring crops, among which cereals represent more than two-thirds, amounted to 202,506,000 acres, or 99 per cent. of the area forecast by the Plan, against 202,597,000 or 97 per cent. at the same date last year. The sowing of spring cereals, which up to May 10 had been carried out on 79 per cent. of the area forecast by the Plan, had exceeded the Plan on May 25 by 2 per cent.

In the European Territory of the Union, the weather in the second decade of May was warm in the south, while in the north the temperature rose only during the second half of the decade. On the whole, temperature in the second decade of May were appreciably lower than normal in the north and slighter higher than normal in Crimea, Ukraina and North Caucasus. There was heavy rain in North Caucasus, the west of Ukraina and in White Russia. There were also good rains in some parts of the centre and part of the north-east.

In the third decade of May cloudy and moderately warm weather prevailed in the southwest and south, with frequent precipitation from storms of short duration and uneven distribution. In the greater part of Ukraina, around Rostov and Krasnodar, and in other parts of North Caucasus, rainfall amounted to from 1 to 2 inches. There was heavy rain also in the Orel, Kalinin and Riazan districts, while in the centre and north rainfall was from  $\frac{1}{2}$  to 1 inch and in some parts even less.

In the first decade of June the weather was variable with heavy rain storms. A wave of cold air from the Polar regions was also accompanied by a sharp drop in temperature. There was heavier rain in the north (1 to 2 inches during the decade), in the west ( $\frac{1}{2}$  to 1 inch), in the Caucasus (1 to 2 inches) and in the Tcheliabinsk area (1 to 2  $\frac{1}{2}$  inches). Heavy rain also fell in the Stalingrad region, in some parts of the Kouybychev and Saratov areas and in the northeast of Ukraina. There was little

rain in the greater part of Ukraina, and in the regions of Rostov, Voroneje, Kursk, and Saratov. As a result of the rather low temperature and the rain, the disappearance of soil-moisture was not rapid. On June 10, the effective amount of moisture was from  $1\frac{1}{4}$  to  $2\frac{1}{2}$  inches in the territory north of the line Minsk-Voroneje and Tcheliabinsk, which sufficed to assure a normal development of crops. In the Crimea and Caucasus soil-moisture reserves had slightly increased, but they had heavily decreased in the greater part of Ukraina.

On June 10, winter rye in the south of Ukraina was in good or in very good condition at the phase of lacteous maturation. Winter wheat was at the phase of lacteous maturation in Crimea, North Caucasus and the south of Ukraina; crop condition varied from good to very good.

In North Caucasus, Crimea and southern Ukraina the crop condition of spring barley and oats was considered good.

In the west and centre the growth of winter and spring cereals proceeded in good conditions. In the north the growth of these crops was checked by the drop in temperature.

In the Asiatic territory of the Union, growing conditions for winter and spring cereals have been good, and in most areas crop condition on June 10 was considered good.

According to the recent reports of the Commissar for Agriculture, the crop condition of cereals at the beginning of June varied from good to very good in most parts of the country and only in a few areas was it considered as only satisfactory.

#### America.

*Argentina:* In May preparations for the sowing of cereals were carried out in good conditions, and, following rain at the end of May, germination improved since the official report of May 3.

*Canada:* Grain crops over most of the Prairie Provinces made a rather promising start in May. With the exception of southern Manitoba, southeastern and parts of central Saskatchewan and southeastern Alberta, spring moisture conditions were quite favourable. Sowing proceeded rapidly during the first ten days of May. In drier districts of the Prairies farmers delayed seeding somewhat, waiting for more favourable soil moisture conditions. High winds caused considerable soil drifting in the second week of May; while damage to crops was not widespread, some localities experienced moderate losses. Rains commencing May 19 and continuing till the end of the month promoted the recovery of drought- and wind-damaged grain. Some reseeded was necessary but was not general. Damage by cutworms and wire-worms occurred in some localities but no extensive losses from insect damage were reported. During warmer and drier weather in the early part of May grasshoppers became quite active but were checked by wet and cool weather in the latter part of the month. The threat of a general outbreak continued, however. Preparations were made to combat outbreaks and poisoning had already been undertaken in some areas.

Crop condition at the beginning of June was generally satisfactory. The first few days of June were cool and wet, which favoured crop development and retarded the activity of grasshoppers, which however still remain a menace over those parts of the Prairie Provinces needing moisture. Heavy rains fell on June 5 and benefited drought affected areas.

The following week continued cool and showery. Precipitation was light, but low temperatures helped to conserve moisture supplies. The weather also aided

in checking grasshopper development and damage from this source was confined to local areas during the week. Wheat crops had lost some of their advantage in earliness as a result of the cool weather, and moderately warm weather in the immediate future was required to promote rapid, healthy development. The only areas immediately in need of moisture supplies were northwestern Manitoba and southeastern Saskatchewan. Northwestern Saskatchewan and southern Alberta showed considerable improvement during the week and crop prospects were now promising in these areas.

Additional heavy rains across the Prairie Provinces during the third week of June further improved crop prospects. The dry areas of northwestern Manitoba and southeastern Saskatchewan received fair benefit from the rains. Temperatures continued low, holding grasshoppers in check. Cereal crop growth has been slow but favourable.

*Chile:* In the following table figures are given for the production of barley and oats during the 1938-39 season, compared with the data for the preceding season and the five-year average ending 1936-37.

	1938-39	1937-38	Average 1932-33 and 1936-37	1938-39	1937-38	Average 1932-33 to 1936-37	% 1938-39 1937-38 = 100	% 1938-39 Average = 100
	thousand centals			thousand bushels

Barley . . . . .	1,664	3,596	2,544	3,466	7,492	5,299	46.3	65.4
Oats . . . . .	3,271	2,655	2,135	10,223	8,295	6,673	123.2	153.2

*United States:* During the first week of June, the temperature was generally above normal and rains were fairly well distributed from the Rocky Mountains eastward. Winter wheat harvesting was started in the southwest and spring wheat was greatly improved by rains.

During the second week the temperature was above normal and there was widely scattered rain. Rain was still needed in the Middle and North Atlantic states and also in the southwestern areas. Winter wheat was improved by the rains in some areas, and harvesting was hindered in others, but little change occurred in Kansas. Spring wheat improved.

During the third week of June there was general rain except in large areas of the southwest and there were marked contrasts in temperature, but the weather was mostly favourable for agriculture. The harvesting of winter wheat progressed satisfactorily but was interrupted by rains. Spring wheat was much improved.

According to a cable of June 10 the production of winter wheat indicated by condition on June 1 was 314,065,000 centals (523,431,000 bushels), a decrease of 12,346,000 centals (20,576,000 bushels) on the estimate issued a month ago. At this level, this year's production of winter wheat would be 23.8 per cent. below the actual outturn of last year but 5.3 per cent. above the 1933-37 average.

The rye crop is expected to amount to 19,392,000 centals (34,629,000 bushels), a decrease of 37.1 per cent., on last year but an increase of 0.5 per cent. on the five-year average.

Condition of spring wheat on June 1 was estimated at 71 per cent. of the normal against 87 per cent. a year ago and an average of 77 per cent. in the ten years 1927-

1936. Condition of oats was estimated to be 72 per cent., compared with 87 last year and a ten-year average of 77 while that of barley, also 72, compares with 87 and 78 respectively.

*Uruguay:* Following the spread of "pulgón verde" (*toxoptera graminis*) in important areas of the country, cereals sowing is retarded and irregular.

#### Asia.

*Chosen:* The first official estimates of wheat and barley production in 1939 are as follows, compared with the final figures of the preceding years.

		1939	1938	Average 1933-37	% 1939 1938 = 100	Average 1939 = 100
Wheat . . . . .	(ooo centals)	7,371	6,290	5,566	117.2	132.4
	(ooo bushels)	12,285	10,483	9,277	117.2	132.4
Barley . . . . .	(ooo centals)	29,315	24,721	25,021	118.6	117.2
	(ooo bushels)	61,075	51,504	52,128	118.6	117.2

*India:* Toward the end of May crop condition was reported to be fairly good on the whole.

In the Punjab in the four weeks ending June 5 the weather was dry except for light rain in parts. Crops were in average condition in irrigated areas and under average to average in unirrigated. In the Central Provinces the weather was hot; in the week ending June 3 it was also cloudy, with light showers in Sagore and Jubbulpore.

*Japan:* The preparation of the land and the sowing of spring cereals were carried out in favourable conditions.

Favoured by the weather, the crop condition of winter wheat was rather good.

*Palestine:* Weather conditions in May were abnormally hot with easterly winds, but during the last week cooler conditions prevailed. Atmospheric humidity was consequently low. No losses due to these conditions were reported, except 5 per cent. in the northern coastal plain. Yields are excellent.

The production of wheat in 1939 is estimated at 3,000,000 centals (5,000,000 bushels against 979,600 (1,632,700) in 1938 and an average of 1,928,800 (3,214,700) in 1933 to 1937; percentages, 306.2 and 155.5.

#### Africa

*Algeria:* May was at first wet. Later the weather became stormy and changeable. Some lodging is reported in a number of areas. Fine sunny days generally checked the spread of yellow rust, but black rust among hard wheat gave some anxiety on the littoral. Nevertheless, the crop condition of winter wheat on June 1 was good; that of soft wheat, oats and rye was average; that of barley was excellent and the first harvesting of this crop in the south gave excellent yields.

The first estimates of cereal production are as follows compared with the final figures of the preceding years.

June 1 estimates of Cereal Production.

	1938	1937	Average 1932-1936	% 1938 1937 = 100	Average = 100
	(thousand centals)				
Hard wheat . . . . .	18,629	13,838	13,946	134.6	135.5
Soft wheat . . . . .	8,267	7,127	6,700	116.0	123.4
<i>Total</i> . . . . .	26,896	20,965	20,646	128.3	130.3
Barley . . . . .	22,267	12,944	16,389	172.0	135.9
Oats . . . . .	4,409	3,486	3,234	126.5	136.3
Rye . . . . .	25	25	18	100.6	141.4
	(thousand bushels)				
Hard wheat . . . . .	31,048	23,063	23,242	134.6	135.5
Soft wheat . . . . .	13,779	11,878	11,166	116.0	123.4
<i>Total</i> . . . . .	44,827	34,941	34,408	128.3	130.3
Barley . . . . .	46,390	26,967	34,143	172.0	135.9
Oats . . . . .	13,779	10,892	10,107	126.5	136.3
Rye . . . . .	44	44	31	106.3	141.4

*Egypt:* Harvesting of the wheat crop was over in Upper Egypt at the end of May, and covered 85 per cent. of the area elsewhere. Threshing and storing were in progress. The yield is apparently satisfactory. Harvesting of the barley crop is over. The results of threshing show that the yield is satisfactory.

*French Morocco:* After a sharp drop in temperature at the end of April, with frost at Fès and Meknès in particular, the first decade of May was marked by rather fine rain and mist in the north and centre and snowfalls in the central Atlas region; later there was a period of *chergui* from May 10 to 15, and finally the month closed with normal temperatures in the coastal area with a little *chergui* in the interior. The growth of wheat continued to be satisfactory and the usual diseases or insect pests are doing only very little local damage. Barley harvesting began in north, central and eastern Morocco, in spite of the lack of labour, and was finished in the Marrakech, Sous, Abda Chiadma and Abda Ahmar districts; yields every where were above the averages of previous years, and in some cases they are exceptional. The grain is large, full and the specific weight high. Increases of 75 to 100 per cent. on the estimates of last year are forecast.

The first estimates of cereal production are as follows, compared with the final figures of the preceding years.

June 1 estimates of Cereal Production.

Crops	1939	1938	Average 1933-37	% 1939 1938 = 100	Average = 100
	(thousand centals)				
Hard wheat . . . . .	14,881	8,057	9,650	184.7	154.2

Barley . . . . .	97,740	49,869	52,819	196.0	185.0
Oats . . . . .	5,236	3,275	1,777	159.9	294.6

*Kenya:* Abundant rains fell during April in all districts except at the coast, where abnormally dry conditions were experienced. As a result, there was widespread planting of cereal crops. Locusts were present in several districts, but damage to growing crops had so far only been slight.

*Tunisia:* The temperature in May remained below normal. Rain was exceptionally heavy and widespread. The excessive moisture assisted the spread of cryptogamic diseases of wheat (husk rust and *piétin*). Early soft wheat suffered most while hard wheat resisted fairly well. Barley is mature; in most areas harvesting began in June. Oats have made good growth.

On June 1 the estimates of cereal production were as follows, as compared with the final figures of preceding years:

*Estimates of Cereal Production.*

	1939	1938	Average 1933-37	% 1939	
				1938 = 100	Average = 100
(thousand centals)

<i>Total . . . . .</i>	<i>18,555</i>	<i>13,963</i>	<i>13,117</i>	<i>132.9</i>	<i>141.5</i>
Barley . . . . .	16,076	4,593	8,222	350.0	195.5

*Union of South Africa:* In the southwest of Cape Province only scattered showers fell in April. Ploughing for cereal crops was held up until the real winter rains should come.

**Current information on Maize.**

*Bohemia-Moravia (Protectorate):* The area under maize in 1939 is estimated at 22,800 acres against 22,000 acres in 1938; percentage 103.9.

*Bulgaria:* Weather conditions in May were on the whole favourable for maize sowing, which was carried out in good conditions. Following rain the growth of crops also continued in good conditions.

*Italy:* In several districts the sowing of maize was not finished by the middle of May owing to rain. The very heavy rain of the second half of the month hampered late sowings. Growth is affected to some extent by excessive moisture and too low temperatures.

*Romania:* On June 20 maize was growing normally, and crop condition was better than in the last few years at this period. In two mountain departments, crops suffered from hoar-frost, which occurred on June 7 and 8.

*Argentina:* The harvesting and the threshing of maize, favoured by weather conditions, were in full swing at the beginning of June. The second estimate, made on June 7, of maize production in the 1938-39 season (113,538,000 centals or 202,748,000 bushels shows) a reduction of 5,500,000 centals (9,800,000 bushels) on the previous estimate and, while 16.4 per cent. above the exceptionally low figure of last season, (97,532,000 centals or 174,166,000 bushels) is well below (—41.5 per cent.) the average of the previous five years (193,978,000 centals or 346,391,000 bushels). The unsatisfactory result of the 1938-39 season is partly due to the reduction in the sown acreage compared with last season (—14.5 per cent.) and the average (—21 per cent.) and partly to the unfavourable season, particularly the drought and the excessively high temperature during sowing and growth.

*United States:* There was fairly heavy and widespread rain in the first half of June, which was favourable for maize crops. But in the third week further wet and cool weather tended to check growth.

*Hungary:* Early crops in mid-June had a generally good appearance; development of late crops, which had germinated well and uniformly, was hindered by rain and cold. In some places there were complaints of weeds. Sun was needed for satisfactory development.

*Netherlands Indies:* Java and Madura. — The Department of Agricultural Statistics of the Central Statistical Office communicates the following details on the maize area:—

	1939 acres	1938 acres
Area harvested in April . . . . .	95,400	135,200
Area harvested from January 1 to April 30 .	2,477,300	2,408,600
Area of standing crops at the end of April .	1,002,800	992,400

*Algeria:* The first part of May was wet. Later the weather became stormy and changeable. The crop condition of maize on June 1 was average.

The area under maize in 1939 is estimated at 15,600 acres against 14,900 acres in 1938 and an average of 18,100 acres in 1933 to 1937; percentages, 104.4 and 85.9.

*French Morocco:* In May maize and sorghum were sown in eastern Morocco, at Taza and Ouezzane. During the month re-sowing was carried out everywhere where a return of cold weather had caused excessive loss. Crop development, favoured by rains during the month, is very satisfactory.

*Tunisia:* In May and at the beginning of June the temperature remained below normal. Rain was exceptionally heavy and widespread. Conditions were favourable for the first growth of maize and sorghum crops. Sowing was still in progress in some parts.

The area under maize and sorghum in 1939 is estimated at 61,800 acres against 42,500 acres in 1938 and an average of 52,200 acres in 1933 to 1937; percentages, 145.2 and 118.3.

*Union of South Africa:* In April there was a spell of cold weather with snow and frost in the Orange Free State and Transvaal and late maize crops were damaged, but most crops were sufficiently mature to withstand the adverse conditions. The remainder of the month was dry and warm. Conditions in Natal were favourable.

### Current information on Rice.

*Italy:* In May the growth of rice was retarded owing to low temperatures. Seasonal work began.

*British Guiana:* It was reported in April that the milling of the rice crop was being hampered by the excessively wet weather.

*Taiwan:* The transplanting of first crop rice is finished. Growth continues in good conditions.

*India:* In Bengal in the last three weeks of May and the first week of June rainfall was generally light to moderate. Sowing was proceeding briskly and at the beginning of June weeding was in full swing.

In Bihar light rain fell in a number of districts and heavy rain in Purnea. In Orissa light rain was also general.

In Assam in the four weeks ending June 12 the weather was seasonable but there was some need of rain.

In the Central Provinces the weather was hot; in the week ending June 3 it was also cloudy, with light showers in Sagore and Jubbulpore.

In Madras, where sowing was proceeding, there was heavy rain in Tanjore in the week ending May 13, fair rain in parts of the Centre and light rain in the Circars in the following week, moderate rain in the central districts and on the west coast in the week ending May 27 and moderate rain in general in the subsequent week.

*Netherlands Indies:* Java and Madura. — The Department of Agricultural Statistics of the Central Statistical Office communicates the following details on the rice area:—

	1939 acres	1938 acres
<i>Area harvested in April:—</i>		
Wet padi . . . . .	1,212,300	1,127,600
Dry padi . . . . .	443,600	400,000
<i>Area harvested from January 1 to April 30:—</i>		
Wet padi . . . . .	2,005,300	1,919,500
Dry padi . . . . .	773,000	815,200
<i>Area of standing crops of the end of April:—</i>		
Wet padi . . . . .	5,756,400	5,835,200
Dry padi . . . . .	146,500	131,000

*British Malaya:* During March the weather was dry in most localities. Showers and storms occurred and the total precipitation approximated to normal. Showers became more frequent during the last part of the month.

The harvest was still proceeding in Krian. Yields were said to be slightly higher than last year, but quality was reported to be rather poor. As planting was not carried out simultaneously, harvesting was expected to continue over a long period.

In Malacca yields were generally rather lower than last season but a fairly good crop was reaped in inland areas near Alor Gajah.

The harvest in Kelantan was nearing completion. The dryland padi crop was reported to have been patchy, but in most localities yields were better than last year. Late planted areas were yielding poorly.

*Egypt:* Sowing of summer has advanced during May, 55 per cent. of the total area having been sown. Preparation, sowing, watering and draining were in progress. Weeding was started in early cultivations in some localities. Germination and growth were satisfactory.

### Current information on Potatoes.

*Germany:* The growth of potatoes was retarded somewhat during April and May.

*Belgium:* Potatoes have grown rapidly since subsoil moisture is plentiful. Early varieties are coming on the market sooner than usual.

*France:* Potatoes, which were planted in May in rather poor conditions, rose at first very slowly and irregularly, particularly on heavy, wet land. The Colorado beetle made an appearance among early varieties.

*Hungary:* The rains were beneficial; vegetation was active and of good colour. In mid-June early varieties had in part passed the flowering stage; a certain proportion had been placed on the market.

### Potatoes.

§) For the explanation of signs and figures indicating crop condition, see cereal tables and note on page 515. — a) Above the average. — b) Average. — c) Under average. — s) Early potatoes. — t) Main crop.

*Italy:* At the end of May the planting of main season potatoes was not complete owing to excessively wet weather. Growth was satisfactory.

*Luxemburg:* The dry, cold weather of the second half of May retarded the normal growth of potatoes.

*Netherlands:* Potatoes for direct human consumption developed slowly but, with favourable weather might easily recover. Potatoes for fecula were well developed and despite the drought the majority of the crops had a good appearance.

*United Kingdom:* Little damage was done to early potatoes by frost in England and Wales. The main crop, where already up, is promising. In Scotland planting was carried out in very favourable conditions.

*Switzerland:* The crop condition of potatoes is very variable. In early sown fields the cold, wet weather checked the growth of the tubers, and in those sown after the rains germination is only just beginning. Warm weather could still greatly improve crop condition.

*U. S. S. R.:* In the south and centre of the U. S. S. R. potato planting is finished, but in other areas was still continuing. On June 10 the area planted was 89 per cent. of the Plan, against 98 on the corresponding date last year.

*Argentina:* The lifting of potatoes was still in progress in May, with average yields.

*Algeria:* The first part of May was wet. Later the weather became stormy and changeable. Mildew is reported on main season potatoes. The early potato crop was variable in Oranie, where diseases of degeneracy did serious damage. Elsewhere the crop was average.

## General Review of the Condition of the Sugar-Beet Crop.

In the second half of May cold, wet weather continued in all the European beet-growing countries, so that the growth of beet crops was slowed down. In some cases even night frosts occurred, but these were not very harmful. In the last ten days of May in the northwestern countries the weather was rather variable, now dry and windy, now warm and stormy, now dry and cold, but on the whole with rather less rain than in the remainder of Europe.

Agricultural work in general was carried on with some difficulty and weeding in some cases was not completed, but, while the weather during the month was not always favourable for beet crops, it was not as unfavourable as its exceptional abnormality had caused to fear. In fact at the end of May beet crops were retarded but of good colour, of thick and regular growth and almost free of disease. In some cases, as in certain districts of Poland, the plants did not survive the cold and wet and fields had to be resown, but these were only restricted areas and not of general importance.

At the end of May and in the first days of June the weather turned fine and conditions were more favourable for the growth of sugar-beet. At first the nights were clear and cold but later the temperature rose also at night. The work of cultivation was resumed regularly in spite of the fact that in some areas the hardening of the soil caused by the cold weather of May created some difficulty. Plants resumed growth and even to some extent made up some of their lateness.

In the first half of June the weather was generally warm and sunny but broken, especially in central and northern Europe, by strong winds with local rain and local falls in temperature. The growth of beet was favoured by these conditions and continued almost everywhere in a satisfactory manner. Weeding, hoeing and thinning are in full progress and the fields can be maintained without

*Acreeage of Sugar-beet.*

\* Approximate data. — (a) Not including U. S. S. R. — (b) Including U. S. S. R. — (1) Licht's estimate. — (2) Year 1937.

difficulty. There has been in some cases a local re-appearance of cold weather, with heavy rain and even snow in the mountains of central Europe, but fine weather soon returned.

In the western European countries humidity was less and there was even in some cases drought, but generally beet crops even suffer these conditions without apparent damage, although rain is greatly needed.

On the whole, taking into account the various weather conditions and the reports received by the Institute, it may be concluded that the general condition of beet crops was more promising at the middle of June than at the middle of May.

\* \* \*

In the U. S. S. R. the new figures of the beet area of this year and last year, given in the Table, instead of the figures of the Plan, are calculated on the basis of the percentage of the total area hoed, which was recently published in Soviet journals.

### Current information on Sugar.

*Belgium:* Sugar-beet crops have a good appearance and are growing rapidly, the soil and subsoil moisture being plentiful. Even so, if the drought of the first half of June should continue, crops would suffer. Crop condition on June 1 was good.

*France:* In May sugar-beet rose with great regularity. The first hoeing and separating were carried out in excellent conditions. The area sown for sugar and distillation is very much higher than last year.

*Hungary:* In mid-June growth was good, leafage was abundant and of good colour. Second hoeing of early crops was in progress and late crops were being singled.

*Italy:* In May the growth of sugar-beet was irregular. In some districts resowing was necessary.

*Netherlands:* Crop condition in mid-June was fairly good to good. Only in Nord-Holland and Zeeland had some areas to be resown after the damage caused by *Atomaria linearis*. Crop condition in the system of the country was 66 on June 12, 1939 against 68 on June 13, 1938.

*United Kingdom:* The sowing of sugar-beet was practically completed by the end of May. There is a slight increase in area on last year. Conditions for sowing were favourable.

*Switzerland:* On early sown fields the cold wet weather checked the growth of sugar-beet, and among those sown after the rains germination is only just beginning. Warm weather may still greatly improve crop condition. Crop condition on June 1 in the system of the country was 72 against 69 at the same date last year.

*U. S. S. R.:* According to the Commissariat for Agriculture, hoeing had been carried out on June 10 on 89 per cent. of the areas sown to sugar-beet, thinning on 83 per cent. and inspection on 31 per cent. The corresponding percentages for last year are as follows: 97, 77 and 23.

As a result of the favourable weather conditions of May, beet crops are growing well. At the beginning of June crop condition was good.

During the 1938-39 season, the factories treated 346,000,000 centals (17,300,000 short tons) of beet, yielding 47,400,000 centals (2,370,000 short tons) of sugar.

*Argentina:* The sugar-beet crop this season was very poor, except on irrigated land.

Sugar-cane crop prospects for the season just begun are excellent.

*Barbados:* During April weather conditions were favourable for the reaping of the sugar-cane.

## Production of Cane-sugar.

(1) Approximate data.

*British Guiana:* It was reported in April that large areas were under water due to excessive rains, and some damage to cane crops was feared. Estates, however, were still grinding.

*St. Kitts:* It was reported in April that the young cane crop was looking well but rain was needed.

*St. Lucia:* It was reported in April that all sugar factories were working and results were satisfactory.

*Trinidad:* During April the weather continued favourable for the reaping of the sugar cane, the sucrose content of which was stated to be generally better than that of the last crop. Shortage of field labour however was reported.

*Taiwan:* The growth of cane in the new plantations is proceeding in good conditions and in old plantations in even better.

*Netherlands Indies:* Java and Madura. — In the second half of May the eastern monsoon blew, bringing copious rain, especially in the east of the country. Weather conditions were favourable for agricultural work, especially the planting of the cane.

Wet weather continued in the first half of June, but rain was less in the east of Java than in the centre and west. A large amount of lodging of cane was reported and some difficulty was experienced in the work of cultivation (*Aneta*).

*Egypt:* Growth of the sugar-cane crop is progressing satisfactorily owing to the favourable weather conditions and adequate water. Hoeing, manuring and watering are in progress. Crop condition on June 1 was normal.

*Mauritius:* The production of cane sugar for the season 1939-40 is unofficially forecast at 5,500,000 centals (275,000 short tons) against 7,084,000 (354,200) in 1938-39 and an average of 5,886,000 (294,300) in 1933-34 to 1937-38; percentages, 77.8 and 93.6.

*Union of South Africa:* The production of raw cane-sugar in 1939-40 is estimated at 11,622,000 centals (581,000 short tons) against 11,616,000 (580,800) in 1938-39 and an average of 9,426,000 (471,300) in 1933-34 to 1937-38; percentages, 100.1 and 123.3

### Current information on Vines.

*Germany:* Vines were damaged during the severe frosts and changes of temperature in mid-December. In addition growth is rather retarded owing to the cool weather of the spring of 1939. The general rise in temperature, however in the third decade of May accelerated growth, to such an extent that in all areas the condition of vineyards is better than normal.

The average crop condition in the Reich is 2.6 against 3.4 at the corresponding date of last year. The general appearance of vines justify good hopes for the vintage, owing to the fine weather of June.

*Bohemia-Moravia (Protectorate):* Vines had not been affected by the winter frosts and at the beginning of May crop condition was good.

*France:* Cold wet weather in May checked the normal growth of vines, hampered work and the cleaning of the land and in most cases it reduced the efficacy of the treatment. Strong winds damaged many fruit-bearing buds. In regard to diseases, attacks of mildew are already frequent, particularly in the Narbonnais and the sheltered and badly ventilated valleys of the Bouches du Rhône. On the other hand, appearances of *cochylis* and *eudemis* are not numerous. It is now possible to measure the exact extent of the damage done by the winter frosts. This damage is very severe particularly in Charente. The growth of clusters is very variable.

*Greece:* The preliminary estimates of the area under vines in 1939, compared with that of 1938 and the average of the years 1933 to 1937 are as follows:—

*Area under Vines in Greece.*

	1939	1938 (acres)	Average 1933-1937	% 1939 = 100	Average = 100
Vines:					
for wine grapes . . . . .	388,780	392,000	367,110	99.2	105.9
for table grapes . . . . .	45,830	48,800	47,110	93.9	97.3
for dried grapes . . . . .	198,020	198,580	187,330	99.7	105.7
<i>Totals . . . . .</i>	<i>632,630</i>	<i>639,380</i>	<i>601,550</i>	<i>98.8</i>	<i>105.4</i>

*Hungary:* The higher temperatures in the second half of June greatly improved crop condition, which had been badly affected by the cold rainy weather of the preceding weeks. In the vineyards of the hotter districts flowering had already begun. *Peronospora* had appeared practically everywhere but without so far causing damage.

*Italy:* The growth of vines was on the whole good in May. Nevertheless, damage was feared if the weather should continue wet and cool.

*Luxemburg:* The excessively low temperatures of May had an unfavourable effect on the growth of vines.

*Switzerland:* Owing to the cold weather of May the growth of vines is about two weeks late. Sprouting was normal, but later growth slowed down. So far crop prospects are favourable, particularly as there have been no spring frosts. If blossoming takes place in good conditions, the yield of vines will be satisfactory. Crop condition on June 1 in the system of the country was 68 against 39 at the same date last year.

*Argentina:* It is confirmed that grape production this season is lower than last year in Mendoza and Río Negro Territory, following damage done to vines by frost and winds. However, the production of these two viticultural centres may be considered satisfactory. The drought of January and February very seriously damaged vines in San Juan. Grape production in Salta and Jujuy, though lower than last year, is considered satisfactory.

*Algeria:* May was wet at first and later was stormy. Flowering took place in good conditions.

*Tunisia:* Frequent rain in May and June assisted the spread of cryptogamic diseases among vines (mildew and *oidium*), against which viticulturists waged an energetic campaign with sulphur sprays and dustings. The flowering of vines at the beginning of June was in progress or already finished.

**Current information on Olives.**

*France:* In May the blossoming of olive-trees had hardly begun in favoured localities. The number of clusters is everywhere high but buds are less numerous than usual except in Languedoc and Roussillon, where the crop was poor in 1938.

*Greece:* The weather in the second half of April and the first half of May was very favourable for the growth and flowering of olive-trees in almost all the producing areas of Greece. Measures were being taken to combat *dacus*, and it was hoped to

reduce damage to a minimum. Oil production at present is reported to be very satisfactory, particularly in Corfu, Euboea and Crete. The rather wet weather of the second half of March and the first decade of June had not affected the condition of olive trees.

*Italy:* The growth of olive-trees was good in May.

*Argentina:* Olive picking was still in progress in May. The crop is of good quality and yields on the whole are considered satisfactory.

*Algeria:* The flowering of olive trees was finished in May. Although growth is late, it is hoped that the future crop will be large.

*French Morocco:* The blossoming of olives, which took place in May in good conditions, promises a good crop.

*Tunisia:* In May the temperature remained below normal. Rain was exceptionally heavy and widespread. The flowering of olive trees was satisfactory. In the south, however, fruit formation was rather irregular owing to variable weather and attacks of false puceron. The growth of trees is good. Crop forecasts are good or fairly good.

### Current information on Flax.

*Finland:* The production of flax in 1938 is estimated at about 2,218,500 lb. against 2,278,000 lb. in 1937 and an average of 3,551,900 lb. in 1932 to 1936; percentages, 97.4 and 62.5.

*France:* The growth of flax, checked at first at the beginning of May by unfavourable weather, became vigorous towards the end of the month following the rise in temperature. The area under flax is about 120,000 acres. Condition is now fairly good although certain crops have been invaded by flea-beetles and mustard.

### Area and Crop Condition of Flax.

†) For the explanation of signs and figures indicating crop condition, see cereal tables and notes on page 515  
a) Above the average. — b) Average. — c) Below the average.  
1) « Dolgunetz » variety grown for linseed and fibre.

*Hungary:* Flax for fibre had a very satisfactory appearance in mid-June and showed vigorous growth. The rise in temperature in the second half of the month stimulated growth of flax for seed, which was, however, thin in many places.

*Ireland:* May was exceptionally dry with very low night temperatures for the greater part of the month. Flax crops made satisfactory progress.

*Italy:* In May the growth of flax was normal.

*Netherlands:* Flax has suffered greatly from drought, especially where sown late. The stems are generally very short.

*U. S. S. R.:* On June 5 the sowing of flax for fibre (Dolgunez variety) was practically completed in the principal producing areas of the Union. The area sown to the above date was 4,352,000 acres, or 99 per cent. of the Plan, against 4,461,000, or 99 per cent. of the Plan, to the same date last year.

Flax sowing was carried out more rapidly than last year and the condition of the seedlings is good almost everywhere. At the end of the first decade of June flax was flowering in White Russia and western Ukraina. In eastern Ukraina flowering had begun. Crop condition was considered satisfactory.

*Argentina:* In May preparation of the land for flax sowing was carried out in good conditions. Following rain at the end of May, germination improved in the flax belt in the north of the country.

### Current information on Cotton.

*Italy:* In the first half of May the sowing of cotton was nearly completed. In the second half of the month growth was checked to some extent by unfavourable weather.

*U. S. S. R.:* On May 10 the Plan for cotton sowing had been practically completed; 4,883,000 acres had been sown, against 4,863,000 in 1938, or 99 per cent. of the Plan in both years. The average area sown in 1933 to 1937 was 4,977,000.

Weather conditions were favourable for crops, and on June 10 cotton in central Asia, according to the report of the Commissariat for Agriculture, was almost everywhere at the stage of bud formation. Crop condition was good in Uzbekistan and Tadzhikistan and on the whole satisfactory in other areas. Earthing up, cleaning and irrigation were carried out in good conditions.

In the areas recently assigned to cultivate cotton (Ukraina, North Caucasus and Crimea) the crop condition of cotton was good at the beginning of June.

*Argentina:* Rain in the second half of April in the principal cotton producing centres of the country interrupted the picking of early varieties. In the Chaco results are considered good in the centre and east and average in the west.

*United States:* During the week ended June 7, conditions generally in the cotton belt were rather unfavourable through cloudy and wet weather and a consequent lack of cultivation over large areas. Temperatures were mostly seasonable, but rainfall was unfavourably heavy. During the following week temperatures were moderately high, and rainfall was frequent in considerable areas. In general, cotton made good progress in western and more eastern portions of the belt, but much of the central area continued too wet. The first cotton bale of the season is reported from Rio Grande City, Texas.

*India:* In the Punjab in the four weeks ending June 5 the weather was dry except for light rain in parts. Crops were in average conditions in irrigated areas and under average to average in unirrigated; there was damage from kutra insects in Gurgaon.

In the Central Provinces the weather was hot; in the week ending 3 June it was also cloudy, with light showers in Sagore and Jubbulpore. In Bombay local scattered showers fell in Guzarat and light to moderate showers in the south of the province. In Sind on June 10 no rain had fallen; sowings continued and germination was good.

*Algeria.* The first part of May was wet. Later the weather became stormy and changeable. Accordingly, the sprouting of cotton seeds was very late and irregular. Moreover, growth was poor owing to rains and cold weather.

*Egypt:* During the latter half of May the favourableness of the weather conditions and the rise of temperature in almost all days of this period had significantly a good effect in accelerating growth and increasing branching. The flower buds appeared increasingly in the early cultivations of the South of Delta and Middle Egypt. The first beginnings of flowers were observed there. Flowering was general in the early cultivations of Upper Egypt where the bolls began formation in Qena and Aswan provinces. Thinning is still proceeding in the late cultivations of the Northern regions and some localities in Upper Egypt (areas sown after winter crops). Crop condition is satisfactory.

Towards the end of May, egg-masses of cotton leaf-worm gradually spread over all the provinces. The attack is still slight and restricted to small patches. The work of picking up the egg-masses before they hatch.

*Nyasaland:* It was reported in April that the cotton crop had been adversely affected by the wet season.

*Tanganyika:* It was reported in April that cotton picking had commenced in the Lake Province with the promise of fair yields. The indications pointed to good crops of cotton in the Northern and Eastern Provinces but in the Tanga Province it was stated to be dependent on further rain.

### **Current information on Hemp.**

*Hungary:* In mid-June the crop was healthy and had made good progress. The crop was dense and the stems high. Flowering had begun in several places.

*Italy:* The total area under hemp in 1939 is estimated at 223,600 acres against 224,600 acres in 1938 and an average of 172,700 acres in 1933 to 1937: percentages 99.6 and 129.5. In May the growth of hemp was normal.

*U. S. S. R.:* The sowing of southern (Italian) hemp, which is cultivated principally in Ukraina and North Caucasus, had been carried out on June 5 on an area of 210,500 acres, or 96 per cent. of the figure forecast by the Plan; northern (Russian) hemp, which is cultivated in the central zone and in Ukraina, was sown on June 10 over an area of 947,600 acres or 83 per cent. of the Plan, against 898,500 acres, or 74 per cent. of the Plan at the same date last year.

*Argentina:* The hemp crop was satisfactory in the province of Santa Fé.

### Current information on Hops.

*Belgium:* The area cultivated to hops this year is about 2,000 acres against 1,840 in 1938 and 2,100 on the average of the five years ending 1937; percentages 111.0 and 97.4.

*Hungary:* In mid-June development was everywhere good and flowering had begun in many places.

*United Kingdom:* Hop bines are mostly healthy and of good colour, but rain would be beneficial.

### Current information on Tobacco.

*Belgium:* The area under tobacco in 1939 is estimated at 6,600 acres against 5,300 acres in 1938 and an average of 7,100 acres in 1933 to 1937; percentages, 124.6 and 93.4.

*Greece:* In eastern Macedonia and Thrace weather conditions in May at first favoured the growth of tobacco plants in most areas, except for certain districts in the Drama region where owing to the fall in temperature growth was retarded. In the first days of the second decade of May planting out was carried out in almost all the departments of the prescribed area. At the same time the third and last ploughing and harrowing of the fields were undertaken with special care. The humidity of the soil greatly assisted the rooting of the plantations in all departments. Heavy rain-fall in all parts of central and western Macedonia in the third decade of April and the subsequent rise in temperature had considerable influence on the growth of plants by assisting the execution of preparations of the land: ploughing, harrowing, etc. These favourable conditions for the crops also assisted planting out. In the mountain zones this work, having first been begun locally spread rapidly from the second decade of May onwards and was expected to be completed by mid-June. Crop forecasts are now very favourable in regard to quantity.

In Thessaly and Phiotis and Phocis between April 20 and May 20 good rains fell, which greatly favoured the growth of seedlings and also accelerated the preparation of the fields. Seedlings are in good condition, being only slightly affected by diseases. Transplanting proceeded up to the end of May in the most favourable conditions.

*Hungary:* In mid-June the transplanted crop showed vigorous development but much more sunlight and warmth was needed. First hoeings were in progress.

*Italy:* In May the transplantation of tobacco was made difficult by bad weather.

*Argentina:* In May tobacco picking was in progress in the Chaco and in the provinces of Corrientes and Tucumán, with generally satisfactory yields. The drought was unfavourable for crops in the provinces of Córdoba and Catamarca, where yields were low. In the National Territory of Misiones harvesting was well advanced and production was larger than last year.

*Algeria:* Following stormy and variable weather towards the end of May, the preparation of the land for tobacco planting was retarded. At the beginning of June planting out was carried on actively. The plants caught on well.

*Tanganyika:* It was reported in April that the tobacco crop in the Iringa district had improved on earlier expectations.

*Tunisia:* The area under tobacco in 1939 is estimated at 865 acres against 815 acres in 1938 and an average of 1,070 acres in 1933 to 1937; percentages, 106.1 and 80.8.

## Current information on Other Products.

## Cacao.

*Trinidad:* Little cacao was being picked in April and the crop was stated to be short. It was reported that witchbroom was spreading.

*Gold Coast and Togoland under British Mandate:* MID CROP 1939. — It was reported by the end of April that conditions for growth had been mainly favourable throughout the cacao areas and that the mid crop should therefore develop normally. From district reports it was estimated that about 3 per cent. of the crop was already ripe and that 8 per cent would be ripe by the end of May. Some 2½ per cent. had been harvested, of which 1 per cent. had been marketed. It seemed probable that the mid crop would again merge with the early main crop.

The grade percentages of original sampling and check sampling at the ports are summarized in the table below.

*Grade per cent. during April 1939.*

	Original sampling (14,096,000 lb.)	Check sampling at ports (53,321,000 lb.)
I . . . . .	31.2	23.2
II . . . . .	46.9	62.0
III . . . . .	19.3	12.7
Sub-grade . . . . .	2.6	2.1
	<u>100.0</u>	<u>100.0</u>

The percentage of under-fermented beans found in the cacao check samples at ports averaged 15.6 per cent. Stocks in farmers' hands in Ashanti, the Western and Central Provinces were so small that no samples were taken during April; in the Eastern Province where small quantities were to be found samples were taken from 150 lots giving an average purity of about 90 per cent. The average number of beans in the standard 14 cubic inches space bean count during April for all ports was 127.7.

No change was made in the estimate of 18,000 long tons (40.3 million lb.) for the 1939 mid crop, published in the last Report.

MOVEMENT. — Movement statistics for April are given in the following table. Figures refer exclusively to 1938-39 main crop cacao as the amount of 1939 mid crop already marketed was negligible.

	April 1939	April 1938
	(million lb.)	
Railway off-loadings, Takoradi . . . . .	12.7	1.2
Exports:		
Takoradi . . . . .	25.5	1.2
Accra . . . . .	20.4	1.8
Other ports . . . . .	7.9	4.8
<i>All ports . . . . .</i>	<i>53.8</i>	<i>7.8</i>
Eastern Frontier . . . . .	...	0.0
<i>Total exports . . . . .</i>	<i>...</i>	<i>7.8</i>

## Tea.

*India:* In North India in the first half of April droughty conditions prevailed but latterly some useful rain fell in certain areas, though not sufficient for requirements and more is badly needed. Up to the end of April there was a decrease of 4,952,000 lb. on the outturn to the same date last year.

In South India the weather was hot in the earlier part of April but seasonable conditions prevailed later on and crop condition improved. Outturn in south India was 9.33 per cent behind that to the same date last year.

*Japan:* Weather conditions were favourable for tea plantations, the growth of which was normal.

*Nyasaland:* It was reported in April that the tea crop had been adversely affected by the wet season.

*Tanganyika:* It was reported in April that tea had flushed well in the Southern Highlands.

## Coffee.

*Brazil:* The exportable crop of coffee in the 1939-40 season for the period ending March 31, 1940, as estimated by the Departamento Nacional do Café, is 29,843,000 centals. To this figure has been added stocks carried over from the 1938-39 season, amounting to 926,000 centals. The total figure of exportable supplies in the 1939-40 season thus reaches 29,843,000 centals against 31,315,000 last season. In the following table are given the partial figures for the 1939-40 season by states, with corresponding figures for the three preceding seasons.

	1-VI-1939 to 31-III-1940	1-VI-1938 to 31-III-1939	1-VII-37 to 31-III-1938	1-VII-1936 to 31-III-1937
	(thousand centals)			
São Paulo . . . . .	20,909	19,524	23,188	17,590
Minas Geraes . . . . .	4,112	5,216	5,763	6,080
Espírito Santo . . . . .	1,254	1,448	1,753	2,320

<i>Total exportable production</i> .	29,843	31,315	33,681	28,460

In a Congress of the coffee producing States of Brazil, held under the auspices of the D. N. C., a biennial plan covering the 1939-40 and 1940-41 seasons was adopted. The plan envisages a series of measures to be taken with the object of restoring equilibrium between exports and the capacity of absorption of the world coffee market,

while arrivals of coffee at the ports of shipment will also have been regulated. These measures may be summarized as follows:

(1) For deliveries of common qualities of coffee (*despachos comuns*) of the 1939-40 season an equilibrium quota has been fixed at 30 per cent. of the total, which will be purchased by the D. N. C. at the price of 2 milreis per bag of 60.5 kilograms gross, including the bag. This quota must consist of coffees not inferior in quality to grade 8 or with a maximum of 1 per cent. impurities.

(2) For deliveries of better quality coffee (*despachos preferenciais*) of the same season an equilibrium quota of 15 per cent. of the total has been fixed; the grades and types of coffee will be decided by the D. N. C.

The coffee definitively acquired by the D. N. C. must be eliminated from the market, except that used for industrial purposes or advertising.

Arrivals at the ports of shipment have been regulated by the D. N. C. so that the respective stocks in the 1939-40 commercial season will be maintained within the following limits: Santos 291,000,000 lb., Rio and Nitcheroy 93,000,000 lb., Victoria 40,000,000 lb., Paranaguá 20,000,000 lb., Angra do Reis 13,000,000 lb., Bahía 8,000,000 lb. and Recife 6,500,000 lb., a total of 471,000,000 lb. The D. N. C. is authorized to raise or lower the relative amounts at the various ports according to the world requirements of coffee. In addition, the Congress of coffee states reaffirmed the ban on new plantation in Brazil and settled the general lines of the domestic and foreign coffee policy to be followed by Brazil for the increase of coffee exports. For the 1940-41 season the equilibrium quotas will be fixed by the D. N. C., whose existence has been prolonged to June 30, 1941, after having heard the Advisory Council of the Coffee States.

*Netherlands Guiana:* The condition of coffee plantations in April was generally good.

*Dominican Republic:* The weather has been very favourable for coffee picking. A very large crop for 1938-39 is confirmed.

*Venezuela:* Coffee crop forecasts in 1939-40 are excellent. The total area of coffee plantations is 1,000,000 acres, of which 740,000 are in bearing.

*French Equatorial Africa:* The exportable coffee crop in 1939 is officially estimated at 57,700 centals, against 48,600 actually exported in 1938. The total area of coffee plantations in 1939 is estimated at 31,900 acres, of which 22,300 are bearing.

*Nyasaland:* The crop condition of coffee plantations on April 1 was average.

*Sierra Leone:* The condition of coffee plantations on April 1 was considered average in the country as a whole.

*Tanganyika:* It was reported in April that good coffee crops were forecast from the Northern Province and the Mbeya district. Coffee picking was in full swing in Bukoba.

*Hawaii:* The weather in April was favourable for coffee crops, the condition of which on May 1 was considered good.

## Groundnuts.

*Argentina:* The groundnut crop was good in Santa Fé and Entre Rios. Quality is satisfactory. In Córdoba yields vary from mediocre to good. In Salta and Tucumán yields are considered satisfactory.

*Netherlands Indies: Java and Madura.* — The Department of Agricultural Statistics of the Central Statistical Office communicates the following details of the groundnut area:—

	1939 acres	1938 acres
Area harvested in April . . . . .	20,000	31,100
Area harvested from January 1 to April 30 . .	159,400	171,700
Area of standing crops at the end of April . .	197,900	223,400

*Egypt:* Sowing of the groundnuts crops was proceeding in late areas. Hoeing and watering of other areas were in progress. Germination and growth were satisfactory.

*Tanganyika:* Although the groundnut position was reported to have improved in the Lake and Western Provinces, it was anticipated in April that the production would be below the average of the past five years.

### Colza and Sesame.

*Bohemia-Moravia (Protectorate):* In some areas colza was damaged by the winter frosts. At the beginning of May, however, crop condition was good.

The area under colza and rape in 1939 is estimated at 9,200 acres against 9,700 acres in 1938; percentage, 95.0.

*Hungary:* In mid-June growth of colza was vigorous; for the country as a whole a good average crop was in prospect but more warmth and sunshine was needed for satisfactory ripening.

According to the most recent estimate, the area cultivated to colza this year will be about 27,200 acres against 28,000 in 1938 and 24,000 on the average of the five years ending 1937; percentages 96.9 and 113.3. The corresponding production is estimated at about 222,700 centals against 251,200 and 169,100; percentages 88.6 and 131.7.

*Netherlands:* In mid-June colza had not recovered from the cold weather of the first period of growth. Crop condition was 51 on June 12, according to the system of the country, against 35 on April 17, 1939 and 77 on June 13, 1938.

*Poland:* Crop condition of winter colza on May 15 in the system of the country was 3.0 against 3.5 at the same date last year.

*India (Telegram of May 30):* According to the final estimate area cultivated to rape and mustard this year was about 5,462,000 acres against 5,461,000 in 1937-38 and 5,745,000 on the average of the five years ending 1936-37; percentages 100.0 and 95.1. The corresponding production is estimated at about 20,541,000 centals against 22,938,000 and 21,638,000; percentages 89.6 and 94.9.

### Current information on Fodder Crops.

*Germany:* The condition of fodder crops was better than in previous years except in the case of clover.

*Belgium:* Meadows, which were already damaged by frost last December, are now suffering from drought. Clover crops are in the same condition.

*Bohemia-Moravia (Protectorate):* Clover was seriously damaged by winter frosts in some areas, particularly red clover. At the beginning of May permanent meadows were making good progress, but like other crops, were in need of warmer weather.

*Finland:* Fodder crops came through the winter badly, and clover has been extensively damaged.

*Greece:* The area under clover in 1939 is estimated at 36,000 acres against 32,000 acres in 1938 and an average of 27,000 acres in 1933 to 1937; percentages, 111.4 and 134.0.

*Hungary:* The first cut of clover and alfalfa gave very satisfactory results in many districts; in some areas quality suffered from the rains that fell while the crop was still in the fields. Fodder beet had abundant leafage and good colour. Permanent meadows had a good appearance and, where not flooded, promised good unit-yields. In the middle of June haymaking was proceeding.

Pastures are well supplied; growth is excellent.

*Ireland:* May was an exceptionally dry month. The hay crop suffered, but the extent of the damage has not yet been ascertained.

*Italy:* The weather in May caused some delay in the cutting of meadows: hay-making was hampered by rain, which in some districts damaged the hay. The growth of pastures at the end of the month was good.

*Latvia:* Owing to the cold weather of May and at the beginning of June, there was little grass on pastures, certainly much less than usual and than last spring. Abundant supplies of fodder, however, from last year are available and stock are not short of feed.

*Netherlands:* Red and white clover crops are in such poor condition as a result of the severe cold and persistent drought that it is doubtful if they can recover. The condition of permanent meadows is also poor. The condition of alfalfa on the other hand is fairly satisfactory. The quantity of the hay crop is poor but the quality is good.

*Romania:* The first cutting of permanent meadows gave a good yield. On June 20 pastures offered a good feed for stock.

*United Kingdom:* Except for cold, wet spells at the beginning and middle of the month, May was dry, sunny and warm. Rain was needed at the beginning of June. Pastures which were fairly fully stocked in May improved during the month in England and Wales, but were still bare for the time of year. Hay yields however, both of rotation and permanent meadows were forecast as about average. The germination of mangels and turnips and swedes, if slow, was mostly fair to good.

In Scotland pastures were rather bare and backward for the season and were in need of rain at the beginning of June.

*Sweden:* Fodder crops wintered well but growth was hampered by unfavourable weather conditions in May.

*Switzerland:* In spite of bad weather grass made good growth on permanent and rotation meadows, so that a satisfactory quantitative crop of hay may be anticipated. The best hay, however, the May crop, will be lacking this year, but if the weather allows, the quality will still be satisfactory. Frequent rain had an unfavourable effect in the mountains, where cold weather checked growth, so that in many districts there was a shortage of feed supplies, aggravated by the fact that hay crop forecasts were low. Moreover, the climb up to Alpine pastures was considerably retarded. In

a) Above the average. — b) Average. — c) Below the average. — d) Excellent. — e) Good. — f) Average. — g) Bad. — 1) Including Ostmark (Austria) and Sudetenland. — 2) At the middle of the month. — 3) At the middle of the preceding month. — 4) Sown grasses, including clover. — 5) Tame hay. — 6) Wild hay.

the Plateaux hay-making began generally in the first week of June. The crop is good to very good in quantity. The quality, owing to growth having taken place in wet weather, is rather unsatisfactory.

*U. S. S. R.:* The area of permanent meadows in the Union is estimated at about 120,000,000 acres. A good crop is forecast in most areas.

At the end of May the cutting of hay had begun in the south and on June 10 had been effected on 3,100,000 acres.

*Egypt:* Last cutting of bersim was progressing at the end of May. Filling of grains was advancing in areas left to seed formation. Early sown areas were maturing. It was expected that the hot weather prevailing would bear on formation of seeds.

*French Morocco:* After a sharp drop in temperature at the end of April, the first decade of May was marked by fine rain and mist in the north and centre, snowfalls in the central Atlas region; then followed a period of *chergui* from Mai 10 to 15 and finally the month closed with normal temperatures in the coastal zone with a little *chergui* in the interior. Surface and subterranean moisture reserves are still abundant and water-courses are well filled by the melting of the snows. Growth is well advanced and the fodder supplies abundant on all grazings, even in the mountains. Permanent and rotation fodder crops have been abundant but haymaking and gathering were hampered in the north by too wet weather.

## LIVESTOCK AND DERIVATIVES

### Livestock in Bohemia-Moravia (Protectorate).

The following table shows the number of livestock in Bohemia-Moravia (Protectorate) on December 1, 1939, compared with the corresponding figures for December 1, 1938.

Classification	1939	1938	Augmentation (+) or diminution (—)	
Horses . . . . .	273,621	268,102	+	2.1
Asses . . . . .	88	85	+	3.5
Mules and hinnies . . . . .	94	108	—	13.0
Cattle, total . . . . .	2,280,735	2,311,037	—	1.3
cows . . . . .	1,246,523	1,220,560	+	2.1
Sheep, total . . . . .	21,992	25,220	—	12.8
ewes . . . . .	17,315	18,935	—	8.6
Goats . . . . .	591,669	612,880	—	3.5
Pigs, total . . . . .	1,607,191	1,949,034	—	17.5
brood sows . . . . .	217,836	267,440	—	18.5

### Slaughterings and Meat Consumption in Poland in 1938.

The following table gives the numbers of animals slaughtered in 1938 according to the monthly reports of the veterinary service on slaughter-houses under veterinary supervision and of the reports of the local authorities on slaughter-houses not under veterinary supervision.

*Slaughterings (in thousands).*

Years	Cattle			Pigs	Sheep and goats	Horses
	Total	Calves	Other			
1938 . . . . .	3,902.7	2,492.9	1,409.8	5,880.0	750.4	9.0
1937 . . . . .	3,903.2	2,468.4	1,434.8	5,564.3	707.1	10.0
1936 . . . . .	3,598.0	2,340.8	1,257.2	5,012.4	734.0	10.9
1935 . . . . .	3,355.5	2,184.0	1,171.5	4,712.3	672.4	7.5
1934 . . . . .	3,158.6	2,077.1	1,108.5	4,455.3	607.4	5.8
1933 . . . . .	3,551.0	2,142.0	1,409.0	4,195.0	533.0	8.0
1928-1932 (average) . . . . .	3,536.3	2,204.8	1,331.5	4,219.9	653.0	15.9

In comparison with 1937 there was an increase of 1.7 per cent. in slaughterings of cattle specially of the other and one of 9.0 per cent. in those of horses; slaughterings of sheep and goats increased by 6.1 per cent. and those of pigs by 5.7 per cent.

Taking into account the net export of meat and meat products, the consumption of meat per capita is as follows:

*Consumption per capita (lb.).*

Years	Total meat	Beef	Veal	Pigmeat	Mutton	Horse-meat
1938 . . . . .	49.34	13.29	4.10	31.26	0.66	0.02
1937 . . . . .	47.44	13.36	4.08	29.37	0.62	0.02
1936 . . . . .	44.60	11.99	3.90	28.06	0.64	0.00
1935 . . . . .	42.37	11.09	3.62	27.09	0.57	0.00
1934 . . . . .	41.03	10.63	3.48	26.35	0.55	0.02
1933 . . . . .	40.37	13.27	3.53	23.06	0.46	0.04
1928-1932 (average) . . . . .	41.34	13.05	3.35	24.25	0.60	0.09

Average consumption of meat per capita rose by 1.90 lb. or 4.0 per cent. with respect to the previous year. The increase was especially marked for pork 6.5 per cent. and of mutton 7.1 per cent. and slowly for veal (0.5 per cent.). That in beef there was a decrease very slowly of 0.5 per cent.

**Wool Production in Australia.**

Wool production (greasy basis, wool clip plus skin wool) in Australia in the year ending June 30, 1939 is provisionally forecast at 950,000,000 lb., against 1,006,624,000 lb. in 1937-38 and 982,831,000 lb. in 1936-37. This season's figure is the lowest since 1930-31. Production in the three previous seasons had been steadily rising, as sheep numbers rose to the record of 113,373,000 on December 31, 1937. This year's poor yield is due to the very unfavourable season, with severe drought in the last half of 1938, especially in Victoria. There was also a very dry season in Western Australia and drought until the end of October in New South Wales.

Livestock and Poultry in Yugoslavia. <sup>1)</sup>

## The Production and International Trade of Preserved Milk.

The short time that milk in the natural state remains fresh excludes trade between distant countries. To make such trade possible, milk must be preserved. There are a variety of processes for preserving milk. One method is sterilization, by which bacteria are destroyed but the form of the product changed as little as possible. Another is condensation or evaporation, with the addition of sugar, if desired; in this case the milk remains more or less liquid and must be hermetically sealed in a container until it reaches the consumer. The terminology adopted for these products is not uniform between different nations. For example, the term evaporated milk in North America is used for unsweetened, condensed milk, while elsewhere this expression signified a com-

paratively small degree of evaporation. Finally, by removing the water the milk can be completely desiccated. Dried milk is marketed in the form of powder, in blocks or in loaves. The processes of milk preservation may be applied to whole milk, to skim milk or buttermilk. For dried milk, skim milk results in the best conservation. In this survey only milk preserved with partial or total removal of water will be considered. Sterilized milk will be excluded, in so far as national statistics permit it.

The principal preserved milk producing countries are those of the temperate zone, which have a large milch cow population and a scientific and well equipped dairy industry. By means of milk preservation these countries can dispose of sudden excesses of milk production over and above their own normal requirements. Conversely, countries with few or insufficient livestock, particularly tropical countries, can acquire by this means supplies of this nutritious foodstuff.

Statistics of preserved milk production are available for the most important producing countries. In the accompanying table we give, in addition to the latest statistics, corresponding, though often approximate, figures for 1927.

The largest preserved milk producing country is the United States, where there has been a very large increase in the last ten years. By far the greater part of the produce is consumed within the country. Exports in the period here considered have declined considerably, so that only 2 per cent. of the total production is now exported to outlying territories of the United States and foreign countries. Even so, this quantity is so large that the United States occupies second place among preserved milk exporting countries.

The position is reversed in the case of the Netherlands, which is the largest exporting country. There four-fifths of the total production is exported, so that only a small proportion remains for internal consumption.

Very considerable increases in production have taken place in the United Kingdom and Germany. Only in the case of Switzerland is a very considerable reduction seen; however, the lowest level was reached by 1936 and the figures for 1937 and 1938 show a recovery.

The aggregate world production of preserved milk about 1927 averaged 3,300 million lb. and has now reached about 4,400 million lb.

The classification adopted for the various kinds of preserved milk in foreign trade statistics vary very widely between different countries. In many cases no separate statistics are made of condensed and dried milk. The distinction between these two categories has been made as far as possible in the accompanying trade tables. The statistics of dried milk are however included in those of condensed milk in the case of Germany, Algeria, Italy and (for exports only) France.

The first place among exporting countries is occupied by the Netherlands, which alone supplies more than half of the total world exports. It should be

noted that for this country the statistics from 1937 on are not comparable with preceding years because the later figures refer to net weight and the earlier to gross weight. A comparison with corresponding import statistics leaves one to suppose that this change makes a difference of about 20-25 per cent. While the change in the system of measurement does not allow of any precise comparison between the exports of 1937 and of 1936, there is a clear drop between 1937 and 1938.

The exports of the United States and Switzerland have since 1932 remained very much lower than the average of 1927 to 1931. In spite of a certain increase in Swiss exports in 1938, the general trend gives the impression that the exports of these two countries have become more or less stabilized at their present low level. The reason for this decline is different in the two cases. In the United States it was accompanied by a large increase in production and is therefore caused by a development of domestic consumption. In Switzerland on the other hand it coincided with a very sharp falling off in production. Danish exports have also declined to an appreciable extent.

The condensed milk exports of Japan and New Zealand have risen greatly during the period under consideration. Japan's exports are now larger than her average imports in the period of 1927-1931, which is a remarkable result considering the numbers of her milch cows. The figures for British Malaya probably refer exclusively to re-exports.

As in the case of other dairy products, the United Kingdom is the largest importing country; it however also exports on a fairly large, if variable, scale

home-produced condensed milk. The remaining imports are predominantly taken by tropical countries. In the period considered there have been certain noteworthy changes in imports. While before 1932 the United Kingdom absorbed about the same amount as the remaining countries together, in 1938, following a sharp drop in British imports and several increases in other countries, the imports of the United Kingdom amounted to only a little over a half of those of other countries.

The total international trade in condensed milk may be estimated from export statistics at about 562 million lb. in 1938 against an average of 750 mil-

lions in 1927-1931, and from import statistics at respectively about 419 million lb. and 622 millions. In spite of this discrepancy, a heavy decline in world trade is clearly emphasized.

For dried milk the number of large exporting countries is smaller than in the case of condensed milk. The Netherlands are again the largest exporter. The comparison between 1937 on and preceding years is again difficult owing to the change in the system of calculation. The decline between 1937 and 1938, however, is even more marked than in the case of condensed milk.

The other four important exporting countries are extra-European countries. Switzerland, in her trade statistics, apart from the category "Milk, condensed and sterilized, etc.", only gives one other category "Lactic flour", which is a more elaborate product than simple dried milk and the export of which in 1938 amounted to 2,897,000 lb.

The United Kingdom imports of dried milk are normally much larger than those of any other country, an exception being the year 1936 when the imports of the United States rose to an extraordinary extent. The imports of the United Kingdom, after declining from 1931 to 1935, have in the last few years risen very considerably, contrary to the trend of condensed milk. The other fairly large dried milk importing countries are not in general the same as the condensed

<sup>1</sup>) 1929-1931. — <sup>2</sup>) 1928-1931. — <sup>3</sup>) 1930-1931.

milk importing countries. This is explained principally by the fact that the conservability of dried milk is lower.

The international trade in dried milk has shown an opposite tendency to that of condensed milk, rising, according to the export statistics, from an average of 62 million lb. in 1927-1931 to 74 million lb. in 1938 and, according to the import statistics, from an average of 43 million lb. to 59 million lb. in 1938.

W. SCHUBRING.

## World Poultry Statistics and Trade in Eggs in the last nine years.

### I. — Statistics of Poultry.

In the contribution of the International Institute of Agriculture to the Fourth World Poultry Congress, which may be considered as a first outline of international poultry statistics (<sup>1</sup>), emphasis was laid on the scarcity of poultry statistics throughout the world and on the serious difficulties encountered in

(<sup>1</sup>) Contribution au IV<sup>ème</sup> Congrès Mondial d'Agriculture: A) Données statistiques sur la production et le commerce de la volaille et des œufs dans différents pays; B) Renseignements techniques sur l'état actuel de l'aviculture dans différents pays. Rome, 1930.

comparing the existing data. Many countries that are very important producers of poultry have no relative statistics whatever, while others publish approximate estimates from time to time without indication of date. However, there have been some notable improvements, and, despite the gaps and imperfections, it is possible to arrive at some general indications regarding the development of poultry culture in recent years.

#### THE CONDITION OF POULTRY STATISTICS IN THE PRINCIPAL PRODUCING COUNTRIES.

Attention may for the present be limited to the most important producing countries, taking them in the order of their poultry numbers.

The first place amongst the producing countries is taken by the United States, which publish on January 1 of each year the number of fowls of three months old and over on agricultural holdings. Owing to the small relative importance of the other species of poultry—geese, ducks and turkeys—this country does not publish annual statistics regarding them. On the other hand, the situation of poultry farming throughout the year is statistically delineated by the Bureau of Agricultural Economics of the Department of Agriculture in Washington in a series of well coordinated estimates: the average number of laying hens per farm flock (on the first day of each month), the average number of chicks and young chickens on hand per farm flock (on the first day of each month) and other statistics concerning prices and the commercial movement of poultry products.

The second rank amongst the world's poultry producers is taken by China, which does not publish annual statistics of poultry numbers. Somewhat incomplete data for the two years 1934 and 1935 only are available. Although these data are not complete they allow at least an approximate determination of the order of importance of poultry in China. As that country is the largest exporter of egg products in the world and a large exporter of eggs in the shell, regular statistics of poultry would be of the greatest importance, not only for China itself but for other countries having commercial relations with it.

The third country in order of importance, the U. S. S. R., ceased publishing poultry statistics after 1929, but the official estimate of 1938 indicates that the numbers in that year were approximately at the 1929 level.

The fourth country, Germany, publishes complete statistics of all species at the beginning of December each year. From 1934 there have been introduced for numbers of fowls two new statistical categories of great value for forecasts of development in the months following the estimate: (1) laying hens of one year and over; (2) young hens under one year. In the present state of poultry culture, in fact, the total numbers have not an absolute importance; the composition by age classes and, if possible, by breeds is, however, of the highest importance.

The fifth place is taken by the United Kingdom, which also regularly publishes statistics, on June 1 of each year, distinguishing two categories of poultry: 1) of age under six months and 2) of age over six months. In recent years a second estimate, at the end of the year, has been instituted, though

for Northern Ireland a total only is given. This second estimate is of the greatest utility, given the ease and rapidity of changes in poultry numbers in the course of the year. Two annual estimates are made by only one other country, Lithuania, which is an exporter of eggs.

Next in order as regards numbers of poultry is France, which, however, does not regularly publish statistics of poultry. The numbers of poultry in Italy, according to the unanimous opinion of various experts, are probably of the same order as those of France but meantime the Italian Government does not publish the relative statistics.

In order of importance follows Canada, which publishes regularly on June 1 of each year complete statistics of all species of poultry. Data for the subgroup of laying hens are also published regularly.

Only slightly inferior to those of Canada are the numbers in Japan, which publishes regularly the statistics of poultry as on July 1 of each year. As subgroups Japan publishes statistics of 1) those under six months and 2) those over six months, both for fowls and for ducks.

The subsequent order, as regards numbers of poultry, of the various countries is uncertain owing to the lack of regular annual statistics. In all probability there follow Poland, Romania, French Morocco, the Philippines and Argentina. Of these countries Poland has only an estimate for 1931 of laying hens, Romania a census in 1934, on February 1, referring to "Poultry that have passed the winter", French Morocco only estimates, the Philippines annual enumerations and Argentina a census in 1930.

<sup>1)</sup> 1934. — <sup>2)</sup> 1929. — <sup>3)</sup> Poultry in general. — <sup>4)</sup> Turkeys and other poultry excluding fowls, geese and ducks. — <sup>5)</sup> 1937. — <sup>6)</sup> 1931. — <sup>7)</sup> 1924. — <sup>8)</sup> Ducks, turkeys, and guinea fowl. — <sup>9)</sup> 1933. — <sup>10)</sup> 1930.

As regards the interpretation of the table the greatest care is necessary. Comparisons between countries are only indicative of the relative importance as regards numbers. Horizontally the comparison is permissible in the strictest sense for the United States, Germany, the United Kingdom, Canada and Japan.

In the seven years considered the numbers of fowls in the United States have oscillated between a maximum of 444.5 millions at the end of 1932 and a minimum of 386.6 millions at the end of 1937; thus the numbers at the end of 1938 indicate a marked recovery. For Germany the figure for 1938 represents the maximum for fowls in the period 1932-38, while that for 1932 is the minimum. While the numbers of geese remain practically constant those of ducks show a certain tendency to decrease in this country.

The numbers of fowls in the United Kingdom oscillated between 69.1 millions in 1937 and 78.5 millions in 1934; the figure for 1938 practically coincides with the minimum of 1937. As in Germany, the numbers of geese in the United Kingdom remained fairly constant while those of ducks showed a downward tendency. The number of turkeys on the contrary increased slowly from 1935 to 1938; in the period under consideration the figure for 1938 was exceeded only in 1933.

The numbers of fowls in Canada oscillated between a minimum of 53.1 millions in 1935; and 59.8 millions in 1932; the figure for 1938 is thus only a little above the minimum. The number of geese and ducks in Canada diminished almost steadily from 1933 to 1938, the latter year being the minimum for both species. Turkeys, which diminished in numbers from 1934 to 1937 showed a slight recovery in 1938.

For Japan the figures indicated in the above table show a maximum in 1932 and a minimum in 1938 for the period considered.

In the following table are brought together the data for several countries of special importance for world trade even though their numbers are not very large. Numerically the first place is taken by the Netherlands, which is the second exporter of eggs in shell. This country regularly publishes statistics of poultry (in May-June) for fowls and ducks, with two sub-groups: a) "born within the year" and b) "others".

The largest egg exporter in the world is Denmark, which has relatively small numbers of poultry but with high laying capacity. The fact that the population is relatively small allows this country to export very large quantities of eggs. It has regular statistics of poultry. It may be noted that in 1929 the Danish statistics also indicated the superior breeds of fowl.

The third place is taken by Belgium, a large exporter of eggs, which has not, however, published statistics except in 1929 (only for adults) and in 1935.

In this group enters also the former Czechoslovakia, which began to publish annual statistics in 1935. For fowls there are three sub-groups: (a) chickens (b) cocks and (c) hens, while all the other species are subdivided only into young and adults. Despite the high production per hen it was necessary to import eggs from abroad.

An important place is occupied by Hungary, which is a large exporter of eggs. It has published statistics only for two years: 1928 and (at a different season) 1935.

Given the irregularity of the series it is possible to make horizontal comparisons only for two countries in the preceding group, namely, Yugoslavia and Ireland. In the former, which is an agricultural country with a not

very intensive agriculture and abundance of cereals, the numbers have all increased while in Ireland, which imports cereals, all the numbers show a tendency to decrease. It is very probable that the position in Yugoslavia is also characteristic of the other Danubian countries.

From the brief examination of the numbers in the most important countries having poultry statistics it is seen that the numbers do not undergo such very great variation as might at first sight appear likely. The countries having an abundance of cereals at their disposal do not find it economically convenient to increase to any unusual extent their numbers of poultry. The egg-importing countries, though desirous of freeing themselves from the necessity of importing, cannot increase their numbers of poultry, as this means feeding a larger number and increasing imports of cereals, but are endeavouring—and this is characteristic of poultry culture in recent years—to maintain the numbers constant or even diminish them, while improving the breeds and thus increasing the unit production.

## II. — Production per Hen and total Production of Eggs in certain countries.

The statistics of egg production in the different countries, both per hen and totals, are of great interest to Governments, poultry farmers, traders and consumers. Although there are real bases for such statistics in the controlled results of the laying competitions and in the diligent records of poultry establishments and of some enthusiastic poultry farmers, it is as a whole generally admitted to be extremely difficult to reach the point of ascertaining the average production per hen per year for any country. The same may be said for the average weight of eggs in any country for any year. The difficulty obviously depends on the large number of holdings in which the poultry are

distributed and on the great variety of breeds and consequent differences in production.

Nevertheless the countries that publish estimates of the numbers of laying hens and relative yield per hen per year are by no means few.

The highest average of eggs per hen per year was attained by the Netherlands in 1938 with the figure of 160 eggs. This is an extremely important result, due certainly to the energetic measures taken by the Government to rationalize poultry culture. For a country to attain such an average means that the unit-yields of individual farmers are very high and that the valuable breeds are widely distributed throughout the country. In the Netherlands themselves in 1937 the average per hen per year was 145 eggs, which had seemed till then to be an unattainable figure. A very high unit-yield was also obtained in Japan for the season from July 1937 to July 1938 with the figure of 135 eggs per hen. Unit-yields of 132 eggs per hen were reached by the Netherlands in 1936 and Denmark in 1935. The average of 120 was attained or exceeded by the former Czechoslovakia (129 in 1936 and 125 in 1937), Ireland (125 in 1936), Luxemburg (123 in 1934), Northern Ireland and England and Wales. Unit-yields above 100 but below 120 have been recorded by Scotland, Belgium, Estonia, Latvia, Canada, the United States despite the vastness of their territory, Palestine and Karafuto. Switzerland estimates the average production per hen at 100, while Germany, which for the preceding years had an average of only 90, reached an average unit-yield of 92 in 1937.

After estimating the average yield per hen per year, the calculation of the total production of eggs is generally based on the number of laying hens, that is, on a determined proportion of the total numbers of hens or on the total number, according to the date of the enumeration. Statistical and livestock experts usually consult both the poultry farmers and the traders in poultry products in order to bring the estimates as close as possible to the facts. The situation of poultry culture varies from country to country and from region to region and the methods of estimate also vary very much from country to country. As a survey of the method adopted by the different countries that carry out enumerations of poultry may be useful both to Governments and to students of poultry problems in general, the International Institute of Agriculture proposes to make such methods the object of a special study.

In the following table are brought together the statistics of egg production in the principal producing countries having such statistics.

The most salient feature of this table is the absolute preponderance of the United States. The production of eggs in that country exceeds the total production of all the other thirteen countries considered.

In reality the relative importance of the production of the United States is less if it is taken into consideration that in the table there do not appear (since they do not publish statistics of production) China, the U. S. S. R., Italy, Poland, Romania, Yugoslavia, Hungary and Bulgaria, which have all a large production of eggs.

The three years of lowest production in the United States, 1934, 1935 and 1936, are certainly to be related to the disastrous drought of the years 1934 and 1936.

*Production of Hens' Eggs in the principal producing Countries.*

<sup>1)</sup> 1929.

For the other countries in the table it may be observed that the estimate for Germany remains very constant, with an increase of 200 millions in 1937, due to the increase in the yield per hen in consequence of the numerous measures taken by the Government for the improvement and rejuvenation of the stock.

Between 1932 and 1937 the production of the United Kingdom showed a distinct tendency to decrease.

In Japan and Canada production remains fairly constant but in 1938 both had relatively low totals. The distinct parallel recovery in the production of the Netherlands and Denmark between 1936 and 1938, while that of Belgium showed a movement in the opposite direction, is noteworthy; it is reflected in the exports of these three countries.

### III. — World Trade in Eggs in the Shell.

Of all the statistics concerning poultry culture those of trade in eggs and egg products are most suitable for international comparisons. From the commercial movement of one country or group of countries it is possible to deduce various indications of the development of poultry culture in the respective country or countries.

For the examination of the commercial movement of eggs in shell 26 exporting countries and nine importing countries have been selected. The quantities exported or imported respectively by these two groups of countries are sufficiently characteristic of the world trade movement. The statistical data considered cover the period of nine years from 1930 to 1938.

## I. — COUNTRIES EXPORTING EGGS IN THE SHELL.

The total exports of the twenty-six countries considered show a diminution from 1930 to 1935 from 1,061,800 thousand lb. to 686,900 thousand lb. Having reached a minimum in 1935, exports began to increase again, attaining 810,590 thousand lb. in 1938. The exports of 1938 are lower than those of 1930 by 251,210 thousand lb., equivalent to about 1,760 million eggs. Shipments in 1938 are thus 11.2 per cent. below the 1930-34 average but exceed by 18 per cent. the minimum of 1935, by 7.4 per cent. the shipments of 1936 and by hardly 1.0 per cent. those of 1937.

Passing to the examination of the individual groups, it is seen that the group of countries most important for world exports, namely, the principal Northwestern European exporters, in 1938 showed a record export for the period under consideration, exceeding by 8 per cent. the 1930-34 average. With respect to 1937, only the Netherlands and Ireland showed a further increase of exports in 1938 while Denmark and the Belgo-Luxemburg Economic Union reduced their exports by 3.4 per cent. and 35.5 per cent. respectively. If 1932 is excepted, the largest exporter in the world, Denmark, showed a decrease in its exports in 1938 for the first time since 1930. The second exporter, the Netherlands, showed in 1938 the largest export of the period under consideration.

The second group, that of the Eastern and Southeastern European countries and the U. S. S. R., rapidly gained ground in 1938, exceeding its shipments of 1937 by at least 5.9 per cent., thanks particularly to Poland and Hungary. The U. S. S. R. had no export of eggs in 1938, while Yugoslavia exported quantities higher than those either of 1937 or of 1936. Of all this group only Hungary was able in 1938 to exceed also the 1930-34 average. This was in large part due to the Hungarian exports to the United Kingdom, which is the largest purchaser of Hungarian eggs. While in the preceding years Hungary exported to the United Kingdom only very small quantities, or none at all (as in 1932 and in 1936), Hungary's exports to that country in 1938 amounted to at least 13,313 thousand lb., more than 42 per cent. of the total Hungarian exports.

An exceptional recovery is shown by the group comprising France and Italy; this group quintupled its 1937 exports in 1938 and its shipments in 1938 were the highest in the period from 1933 inclusive.

The exports in 1938 of the group of three Baltic countries, which are secondary exporters, represent an absolute record for the period 1930-38, thanks particularly to Lithuania. During 1938 the Governments of Estonia and Latvia took very strong measures to promote the export of eggs. The Estonian Government, in order to protect poultry farmers, established a minimum "guaranteed" price by means of a special fund. When internal prices are lower than world prices an export premium is paid to the exporters. When export prices are higher than world prices half of the difference is paid into the "fund" for making prices uniform. The Latvian Government on the other hand has entrusted the collection and export of eggs to a single body, the Central Union of Latvian Dairies.

Exports of the Fennoscandian countries are also in full development and in 1938 established a record for the period considered. In Finland an export pre-

mium on eggs has been introduced. This premium varies with the world price and is fixed by the Government. In Sweden also there is an export premium. All the measures emanating from the Governments of this group have the object of improving the quality of the eggs for the purpose of competing with other exporters.

The exports of the American group show rapid development, particularly through the efforts of Argentina, which on the average of 1930-34 exported only 3,627 thousand lb., while in 1938 its exports increased to 13,537 thousand lb. The exports of the United States in 1938 were lower than in 1937, 1936 or the average. The reduction of shipments from the United States coincides with the commencement of Argentine exports. In fact, in 1930 the largest purchaser of United States eggs was Argentina. With the increase in production in the latter country North American exports in that direction fell off sharply.

The group formed by China and Turkey showed very great reductions in 1938. The former country diminished its exports in consequence of the war and the latter because of the heavy competition on the Central and Western European markets and particularly because of the loss of the Spanish market. The exports of China in 1938 represented only 54.7 per cent. and those of Turkey 15.2 per cent. of the average.

Reductions of almost the same extent as those of the China-Turkey group were also experienced by the African group, comprising French Morocco and Egypt, of which the total exports of 1938 represented hardly 48.7 per cent. of the average.

Australia regularly increased its shipments from 1930 to 1934 and then showed a regular decrease until 1938.

The following table shows the relative importance of each country with respect to the general total.

The most salient feature is the absolute preponderance in world exports of the group of Northwestern European exporters, with a share of 58.3 per cent. of the total. The second group in relative importance is that of the Eastern and Southeastern European countries, of which the participation in world exports has steadily increased from 1935, and which in 1938, with 22.5 per cent. of the total, almost regained the position of 1933. The percentage contribution of France and Italy was in 1938 the highest since 1933. The share of these two countries in the export trade showed a regular decrease from 1932 to 1937, when it touched its minimum. The relative importance of the Baltic and Fennoscandian groups in 1938 was exactly the same as in 1937, when it was much above the average. The group formed by the United States, Argentina and Uruguay gained ground in 1938, when it was responsible for 2.8 per cent. against 1.5 per cent. in 1937 and 2.0 per cent. on the average.

Even if the six preceding groups of countries as a whole acquired added importance in 1938 or at least maintained their 1937 position, the China-Turkey group, the French Morocco - Egypt group and also Australia lost ground both with respect to 1937 and with respect to the average. In fact, their total percentage contribution was only 9.3 per cent. in 1938 against 13.5 per cent. in 1937 and 18.2 per cent. on the average of 1930-34.

As regards the individual countries the largest exporter of eggs in the shell in 1938 remained Denmark, with 26.5 per cent. of the total. It should be observ-

ed that with respect to 1937, when its share was 27.7 per cent., there was an appreciable decline. The second place as exporter is taken by the Netherlands, with 24.0 per cent. of the total, the highest reached by that country in the period 1930-38. The third place is taken by Poland with 7.9 per cent., the highest proportion since 1933. Ireland is responsible for 5.6 per cent., China for 4.2 per cent. and Bulgaria for 4.1 per cent. of the 1938 total.

*Distribution of Exports of Denmark, Netherlands and Poland  
according to countries of destination.*

The exports of the three major exporters, Denmark, the Netherlands and Poland may now be examined.

While until 1932 the exports of Denmark were practically limited to supplying the United Kingdom and Germany, with the accentuation of the economic crisis Denmark was forced to enlarge the range of its exports; already in 1933 it shipped a large quantity to Switzerland and Spain, where previously it had no market. Thanks to the excellent quality of the Danish product, it was able to keep both the Swiss and Spanish markets, the first until 1938 inclusive and the second until 1937.

The principal customer of Denmark remains the United Kingdom, to which, however, in 1938 it no longer exported 85.2 per cent. of its total exports as in 1930 but only 73.3 per cent. The second customer is Germany, where it was able in 1938 to market 24.7 per cent. of its exports, a percentage exceeded only in 1932 (30.3 per cent.). In 1938 the United Kingdom and Germany together absorbed 98 per cent. of the total Danish exports. In 1938 Danish exports to the former country decreased by 9,116 thousand lb. with respect to 1937 while those to the latter increased by 4,233 thousand lb. As the exports to other countries also decreased by 2,677 thousand lb. total exports were 7,556 thousand lb. or 3.4 per cent. below those of 1937. As regards the relatively small quantity exported to "other countries" it may be assumed that the exports to Switzerland and Sweden also diminished notably in 1938 and that the exports to Spain had not yet commenced. However, given the higher price of eggs in 1938 as compared with 1937, Denmark was able to obtain in 1938, despite the decrease in the quantity exported, an export value higher than that of 1937, namely, 139.1 million kronor against 129.3 million in 1937.

The favourable development of Danish exports owes much to the location of the country, in the immediate vicinity of the two greatest importers in the world, the United Kingdom and Germany. However, the exceptional commercial organization and the high quality of the goods must also be taken into account. Although it might seem unlikely, the question of improving the quality of Danish eggs was in 1938 under discussion, with the object of bringing about still further improvements and greater standardization in order to obtain better prices.

The second exporter is the Netherlands, which in 1938 exported 194,642 thousand lb., a quantity 26,740 thousand lb. larger than in 1937. The difference between Danish and Dutch exports was in 1938 only 20,043 thousand lb.

Thus these two countries compete for the first place. The Netherlands find their principal market in Germany and that next in importance in the United Kingdom. From 1936 inclusive the shipments to the latter exceeded those to the former and in 1938 represented 59.6 per cent. of the total export while those to Germany were only 37.6 per cent. These two countries in 1938 together absorbed 97.2 per cent. of the exports from the Netherlands. The fact that Denmark was also able to market in the United Kingdom and Germany 98 per cent. of its exports is an indication of the large absorptive capacity of these

two great importers for the better qualities (like those of Denmark and the Netherlands).

Denmark and the Netherlands find it easiest to export to these two neighbouring countries, leaving the other markets to other exporters. In any case the distribution of Netherlands exports amongst the minor importing countries is such that none of these absorbs even 1.0 per cent. of the total; Switzerland takes only 0.9 per cent. and Spain 0.8 per cent. of Netherlands exports.

The exports of the Netherlands in 1938 were carried out with the assistance of an export premium constituted from the yields of the customs duties on imported cereals. From the economic point of view 1938 must be regarded as a good year for Dutch poultry farming since the prices of poultry feed were rather lower than in 1937 and the average cost of production of eggs was also lower than in that year.

Responsible circles in the poultry industry regard a further improvement as possible by means of eliminating the competition between various exporting firms and establishing a central body to resolve all the problems that arise, in agreement with the Government authorities.

In Poland, the third exporter, exports in 1938 were also very high (61,137 thousand lb.), constituting a record for the period 1933-38. Exports in 1938, however, were much lower than those in 1930, which amounted to 121,500 thousand lb., which means that the production of eggs in Poland might permit a further increase in exports in future years. Poland naturally also directs its exports chiefly to the United Kingdom and Germany. It also exports large quantities, however, to other countries. It is in fact, characteristic of Polish exports to have large numbers of customers of medium importance. Exports of Polish eggs to the United Kingdom remains fairly uniform from one year to another, but show a tendency to increase. The quantity of eggs exported in 1938 to that country (36,580 thousand lb.) was the highest that Poland had ever made and represented 57 per cent. of the total export. The second place amongst purchasers of Polish eggs was occupied in 1938 by Germany and Austria, which took 15 per cent. Italy follows, taking 11.6 per cent. of the total export.

The good results obtained in 1938 were certainly not accidental; rather were they due to improvements in the methods of export and in quality. Eggs of better quality are shipped by preference to Germany and Switzerland.

<sup>1)</sup> Average of 4 years. — <sup>2)</sup> Average of 3 years. — <sup>3)</sup> Average of the totals. <sup>4)</sup> Average of 2 years.

Italy and France were heavy exporters in the period 1925-30 but subsequently reduced their exports from year to year and increased their imports. In 1938, after about six years of this tendency, these two countries diminished their imports and increased their exports more appreciably. The exports of Italy in 1938 rose to 2,094 thousand lb. against 523 thousand lb. in 1937. Notwithstanding the relative smallness of this quantity the revival of exports is in itself significant. Of the total exports 1,080 thousand lb. were shipped to Germany. As regards the imports of eggs into Italy in 1938, Poland was the largest supplier, as in 1937. Next in order as suppliers of eggs to Italy were Yugoslavia and Turkey. As regards France the 1938 export of 5,091 thousand lb. quintals was the largest since 1932. This figure has in itself some significance as regards future development. The largest quantity was sent in 1938 to Switzerland (2,183 thousand lb.). French imports in 1938 were reduced to 24,841 thousand lb. from 34,811 in 1937, the greater part coming from the French Colonies and Possessions and only 750 thousand lb. from foreign countries.

## 2. — COUNTRIES IMPORTING EGGS IN THE SHELL.

The number of importers is much smaller than that of exporters so it is much easier to obtain a clear view of the predominant tendencies. Amongst the few importers the United Kingdom and Germany occupy a position of exceptional importance so that the analysis of their import figures and of the changes in the relative position of the supplying countries from one year to another give a good idea of the world trade in eggs. A characteristic of 1938 was the considerable increase in world trade due to the great increases in the United Kingdom and Germany. The total imports of the eight countries considered rose to 753,483

may be related to the increase in industrial activity, the increase in population and the slower development of poultry culture in the importing countries. In addition account must be taken of the steadily growing knowledge amongst the

masses, of the food value of eggs and of the ease and relative economy of preparing food in which eggs play an essential part. A check on still larger imports is constituted by the necessity of defending the national poultry culture of the respective importing countries and by financial reasons.

As regards individual importing countries, the imports of the United Kingdom, which is the larger importer in the world, amounted in 1938 to 457,969 thousand lb. against 409,155 in 1937 and 362,339 on the average of 1930-34, increases respectively of 11.9 per cent. with respect to 1937 and 26.4 per cent. with respect to the average of 1930-34. The imports of the United Kingdom in 1938 constituted a record for the nine years under consideration.

The imports of Germany <sup>(1)</sup> in 1938, though not strictly comparable with those of the preceding year, show a slight increase with respect to 1937 and a considerable increase with respect to the years 1933-36. The imports of 1938 remain, however, much below those of the period 1930-32, when the German Government had not yet initiated its policy of severely restricting the import of eggs from foreign countries and of intensifying national poultry culture.

Of the other importing countries, Austria <sup>(1)</sup>, Switzerland and Greece increased their imports slightly in 1938, while Italy, France and Czechoslovakia showed heavy reductions. These six minor importers in 1938 imported 19,293 thousand lb. less than in 1937, but the United Kingdom and Germany imported 51,848 thousand lb. more, so that on the whole there was a considerable increase as already emphasized. No official data have so far been published in Spain regarding the trade in eggs.

The relative importance of each of the importing countries in the nine-year period considered is seen in the following table. That of the United Kingdom

*in the Shell. — Imports.*

third rank as an importer. The share of Germany <sup>(1)</sup> was 26.8 per cent. in 1938 against 27.6 per cent. in 1937. The relative importance of the United Kingdom and Germany <sup>(1)</sup> together amounted in 1938 to 87.6 per cent. against 84.3 per cent. in 1937 and 82.4 per cent. in 1930, the year of highest imports in the period under consideration.

*Distribution of Imports of the United Kingdom, Germany and Spain  
according to countries of origin.*

Given the predominance of the imports into the United Kingdom and Germany and the fact that up to 1935 Spain was the third largest importer, the statistics of the imports of these countries are brought together in the following three tables according to countries of origin. From a comparison of the contributions of the various countries to the principal markets, may be seen the potential production and competitive capacity of the individual countries and the tendencies of commercial policy in the importing countries.

In this respect the distribution of the imports into the United Kingdom especially may be considered as characteristic of the entire world trade, since there are no important exporting countries for eggs that do not endeavour to export to the United Kingdom.

The countries of origin with regard to the United Kingdom may be divided into two categories: 1) British countries and 2) foreign countries.

<sup>(1)</sup> See note on the preceding page.

The share of British countries increased from 1930, when it represented 22 per cent., to 1933 (32.7 per cent.) and then fell until 1937, when it was only 14.6 per cent.; in 1938 there was a further slight fall, despite an increase in imports from Ireland, and the British share amounted to 13.3 per cent. of the total. Amongst the British countries in 1938 Ireland increased by about 4,400 thousand lb. with respect to 1937 its shipments to the United Kingdom, but they remained much below the maximum of 1930.

The share of foreign countries on the average of 1930-34 was 72.8 per cent. The maximum was reached in 1938 with 86.8 per cent. of the total.

The principal supplier of the United Kingdom is Denmark, of which the relative importance increased steadily from 1930 to 1934, diminished slightly under the influence of Dutch competition in 1935 and 1936 and reached its maximum of 40.4 per cent. in 1937. In 1938 the importance of Danish supplies fell to 34.3 per cent. owing to the heavy participation of the Netherlands in the imports into the United Kingdom. The second supplier of the United Kingdom from 1930 to 1934 was Ireland but from 1935 that country gave way to the Netherlands, which maintained their position until 1938.

In 1938 Denmark and the Netherlands took a very large share in the imports of the United Kingdom, with about 255,400 thousand lb. of eggs, equal to 55.7 per cent. of the total import. As has already been mentioned, these two countries are seeking to bring the quality of their product and their commercial organization to the highest possible levels in order to maintain their respective positions in the United Kingdom and German markets.

From 1936 the third place in United Kingdom exports has been taken by Poland-Danzig. The fourth place, which in 1937 was occupied by China, passed in 1938 to Ireland. The results of the hostilities in the former country have been felt with increasing force, particularly in the trade in egg products. The imports of the United Kingdom from China were also exceeded in 1938 by those from Finland and from Sweden. Summarizing, in 1938 the principal suppliers of the United Kingdom were Denmark, with 34.3 per cent. of the total, the Netherlands, with 21.4 per cent., Poland-Danzig, with 9.5 per cent. and Ireland, with 8.0 per cent.; these four sources were thus together responsible for 73.2 per cent. of the total imports.

The remaining 26.8 per cent. was supplied by a very large number of countries, in all the continents. As regards the countries for which data are available for 1938 it is worthy of note that Finland has become a steady supplier of good quality eggs to the United Kingdom market. The same may be said of Sweden. Both these countries were able to improve their position in 1938 with respect to 1937 and their combined share of the market rose from 3.4 per cent. in 1937 to 3.6 per cent. in 1938. The relative importance of China fell in 1938 to only 1.1 per cent. against 4.4 per cent. in the preceding year, while that of the Belgo-Luxemburg Union fell from 1.8 per cent. to 0.4 per cent. From the 1937 statistics, which give the most recent complete list of suppliers, it is also seen that Romania was in that year unable to retain the considerable position attained in 1936, its share having fallen from 4.7 per cent. in 1936 to only 2.5 per cent. in 1937. Argentina and Uruguay, which

1933 and 1934.

are suppliers of relatively recent date to the United Kingdom, also showed a decline with respect to 1936 but succeeded in maintaining a fairly good position, with 1.2 per cent. and 0.5 per cent. respectively.

Amongst the new sources of United Kingdom supplies in 1937 may be mentioned Yugoslavia and Hungary, with a joint share of 1.0 per cent. These two countries will probably figure also in the 1938 list, given the fact that the United Kingdom shows increasing interest in the egg production of the whole Danube area (Romania, Hungary, Bulgaria and Yugoslavia) with a view to filling the gap left by the falling off in supplies from China. In this connection the Hungarian statistics for 1938 give the United Kingdom as the principal customer, with 13,313 thousand lb. of eggs in the shell and egg products, while Germany figures with 8,937 thousand lb., Austria with 6,651 and Italy with 1,176 thousand lb. The Romanian statistics for 1938 also record for the first time a considerable export of egg products (3,321 thousand lb., not including eggs in the shell) shipped for the greater part to the United Kingdom.

Germany, which takes the second place in world imports, also possesses a long list of suppliers, of which three are particularly important: the Nether-

lands, Denmark and Bulgaria. From 1930 to 1935 the largest supplier was the Netherlands, in 1936 the first place passed to Denmark, in the following year it was regained by the Netherlands and in 1938 it was again taken by Denmark. The share of these two countries in the German market amounted in all to 48.0 per cent. in 1938, against 45.5 per cent. on the average of 1930-34 and only 33.4 per cent. in 1930, the year of Germany's largest imports in the period under consideration. Bulgaria, though it considerably reduced its shipments to Germany in 1938, still maintained the third place, with 11.5 per cent. of the total. The fourth place, which in 1937 belonged to China, passed to the Belgoluxembourg Union, which succeeded in increasing its share of the German market both absolutely and relatively. It is worthy of note that Ireland, a supplier of recent date in this market, further improved its position in 1938, taking 3.1 per cent. After two years of absence from the German market, Italy reappeared, with 584 thousand lb., in 1938.

It is generally agreed that the German market has a very great capacity but the Government is making strenuous and comprehensive efforts to increase national production and reduce or maintain within moderate bounds imports

into Germany, by countries of origin.

from foreign countries. Increase in the numbers of poultry not appearing desirable, as involving larger imports of feed, the Government is aiding poultry-farmers to improve quality, by means of subsidies, technical advice, the distribution of one-day chicks and the exchange of cocks.

A table similar to those for the United Kingdom and Germany has also been prepared for Spain, which ranked as the third importer up to 1935. Owing to the war, Spanish statistics stop short with 1935 and the first quarter of 1936. In the years from 1936 to 1938 imports of eggs into Spain certainly did not cease though they were very greatly reduced. A reconstitution of Spanish import statistics by means of the statistics of the exporting countries can be accepted only with reserve, there being no certainty that the quantities registered as exported actually reached their destination.

In any case the above table demonstrates that Spain also possesses a very large number of suppliers, amongst whom, on the basis of the 1930-34 average, the first place was occupied by Turkey, with 26.2 per cent. of the total. On the same basis, the second place was taken by the Belgo-Luxemburg Union, with 14.4 per cent., followed by French Morocco with 13.4 per cent. It is noteworthy that in 1935 Poland, Argentina, Bulgaria and Uruguay succeeded in placing appreciable quantities on the Spanish market.

It is certain that it will not be possible in a short time to restore the trade on the large scale attained in 1935, especially since the Government will no doubt make the greatest efforts to increase the numbers of poultry within the country and restrict imports as far as possible. In fact poultry culture in Spain had begun to make good progress, assisted by both college and school instruction.

#### IV. — Forecast of the development of the Egg Trade in the current year and Egg Prices.

In order to have the necessary basic elements for any forecast there have been included in the following table the data of imports into the principal importing countries in the first three months of the current year. The most important fact brought out by this table is the further increase in the imports of the United Kingdom, which represent a record for the period under consideration. With respect to the first quarter of 1938 the imports in the first quarter of 1939 show an increase of 6.2 per cent. and with respect to the corresponding average for 1931-35 one of 54.7 per cent. The exceptionally large increase in Italian imports in this quarter is also noteworthy. Imports into Germany, Austria and Switzerland on the whole remain practically at the same level, those into France, on the other hand, show a decrease. In all, the eight countries under consideration register an increase of 3.5 per cent. in comparison with the first quarter of 1938.

To enable the relative importance of the trade in the first quarter to be evaluated there have been indicated in table XI the percentages of the imports in that quarter to the respective annual totals for the various countries on the average of 1931-35 and for the individual years from 1936 to 1938. On the average and for the single years the quantities imported in the first quarter are less than one-fourth of the annual totals, which is explained by the fact that in this period prices are generally higher than in the succeeding quarters. In 1938 the proportion occupied by the first quarter was 23.9 per cent. As regards the individual countries France regularly imports more than one-fourth of the

<sup>1)</sup> Annual imports = 100. — <sup>2)</sup> January and February only. — <sup>3)</sup> January, February and the first half of March.

year's imports in the first quarter since it takes its supplies for the greater part from the colonies, of which the produce arrives on the market particularly in the winter months and makes up for the smaller home supply. In the first quarter of 1938 Germany also imported more than one-fourth of its year's takings, probably for incidental reasons.

On the basis of these statistics for recent years it seems permissible, even taking into account the international tension, to suppose that for 1939 there will be a further slight increase on the 1938 figures in the volume of trade in eggs in the shell. Such an increase would probably, however, not be very great since imports of egg products from China must in large part gradually be replaced by imports from other countries and this will diminish the available export surplus of eggs in the shell, as in the typical case of Romania.

In order to give a comprehensive idea of the movement in prices for a series of years the average value in gold francs per 1,000 eggs imported into the United Kingdom is given. As this market influences all the other countries throughout the year and takes large quantities of eggs of every quality, these values are indicative of general tendencies. As may be observed from the table, the fall in the price of eggs was followed by a rise, which continued from 1934 to 1938, almost attaining the 1933 level. In fact, prices in all the countries were appreciably higher in 1938 than in 1937, the price of 1,000 imported eggs having been 55.53 gold francs in 1938 against 53.29 in 1937.

XII. — *Prices per 1,000 eggs imported into the United Kingdom.*

Year	Gold francs
1938 . . . . .	55.53
1937 . . . . .	53.29
1936 . . . . .	50.89
1935 . . . . .	49.51
<i>Average 1930-1934</i> . . . . .	86.16
1934 . . . . .	48.61
1933 . . . . .	56.47
1932 . . . . .	68.31
1931 . . . . .	103.56
1930 . . . . .	129.69

The intrinsic qualities of the product are such that, with the progress in poultry culture the trade in eggs has been able to develop and consolidate itself even in a period when international exchanges have been particularly difficult and thus to demonstrate the vitality of the poultry industry and of the trade in its products.

V. DESMIREANU.

**Current information on Livestock and Derivatives.**

*France:* The general condition of stock improves steadily as fodder supplies are becoming more abundant. The first fortnight of June was fairly favourable.

*Latvia:* Milk production again increased in May and is about 3 to 5 per cent. higher than in the corresponding period of last year.

*Netherlands:* In May feeding conditions for livestock were fairly good throughout the country. Compared with the corresponding month of last year, milk production in the country as a whole was about 3 per cent. higher. In North and South Holland production was about 1 per cent. lower, in Zeeland 4 per cent. lower and in Utrecht 7.5 per cent. lower. In the other provinces production was higher as follows: Friesland, Gelderland and North Brabant 3 to 5 per cent., Groningen, Drente, Overijssel and Limburg 7.5 to 10 per cent.

*United Kingdom:* Milk yields were about normal for the season.

*Switzerland:* The early start of pastures, the luxuriant growth of grasses and the fact that the number of cows is relatively large have created favourable conditions for milk production. In April milk deliveries were 4.9 per cent. higher than in April 1938. In May they were 2.2 per cent. higher than in May 1938.

*French Morocco:* Feed for livestock is assured in the south for a long time still by the cereal stubble, already harvested, and, on the whole, the condition of stock is very satisfactory.

*Union of South Africa:* April was generally fairly warm until the end of the month, when it turned cold. There was scattered rain in the winter rainfall areas. Grazing generally was good and the condition of sheep and other stock satisfactory.

**Current information on Sericulture.**

*Italy:* At the middle of June the sericultural season was ending. The last stages were on the whole favourable. Some cases of flaccidity and calcification were reported mainly owing to the very wet season.

The production of mulberry leaves was abundant at the end of May, although a little retarded as a result of low temperatures.

The latest reports indicate that the sericultural season in Italy terminated in fairly favourable conditions. Quality is satisfactory. The deliveries of cocoons to the compulsory collective centres began about the middle of June.

*U. S. S. R.:* On June 13 the Plan for cocoon deliveries in Turkmenistan, the principal producing region, was carried out 12 days earlier than last year. A total of 37,570,000 lb. has been acquired by the State and acquisitions continue.

In 1938 total cocoon production in the Union was 51,400,000 lb.

*Japan:* At the beginning of June the crop condition of mulberry trees was rather good, following favourable weather. The rearing of silkworms progressed in good conditions.

## VARIATIONS IN THE INDEX-NUMBERS OF PRICES

The index-numbers of prices of agricultural and other products of interest to the farmer, as published by the various countries, are often very heterogeneous and consequently great care has to be taken in drawing conclusions from the supplementary information given in the following comparative summary table.

COUNTRIES	Percentage variations in the index-numbers of prices of			
	agricultural products	all products	agricultural products	all products
	May 1939 in comparison with			
	April 1939		May 1938	
Germany (products sold by farmers) . . . . .	+	2.9	+	3.9
Germany (wholesale prices) . . . . .	—	0.5	—	1.9
England and Wales (a) . . . . .	—	8.9	+	2.4
England and Wales (b) . . . . .	—	3.2	—	4.1
Argentina . . . . .	—	0.1	—	1.1
Australia . . . . .	—	5.2	—	16.1
Bohemia c) . . . . .	+	2.1	—	8.6
Bohemia d) . . . . .	+	3.9	+	15.7
Canada . . . . .	—	0.5	+	20.5
United States: Bureau of Agric. Econ. (a) . . . . .	+	1.1	—	15.7
United States: Bureau of Agric. Econ. (b) . . . . .	—	1.1	—	2.2
United States: Bureau of Labor . . . . .	—	0.0	—	3.3
Finland . . . . .	—	2.0	—	5.6
Hungary . . . . .	—	2.0	—	2.6
New Zealand . . . . .	—	0.8	—	4.2
Netherlands . . . . .	—	0.6	+	8.1
Poland . . . . .	—	0.6	—	3.0
Sweden . . . . .	—	1.4	—	5.6
Switzerland . . . . .	+	0.8	+	3.3
Yugoslavia vegetable products. . . . .	+	1.9	—	3.8
Yugoslavia animal products. . . . .	+	3.5	+	2.5

(a) Not corrected for seasonal variation. — (b) Corrected for seasonal variation. — c) Sugarbeet region. — d) Non sugarbeet region.

## EXCHANGE RATES

(1) Parities and current rates are both expressed in U. S. cents (the £ sterling is expressed in dollars). The dollar contains 0.88867 grams of fine gold, i. e. 40.94 % less than formerly. — (2) Former parity. — (3) New parity as from 31 March 1935. — (4) 1 Indochinese piastre = 10 francs: the actual rates vary only slightly from this. — (5) 97 1/2 Egyptian piastres = 1 £ sterling (fixed rate). — (6) New parity as from Oct. 5, 1936.

### ARTIFICIAL RIPENING OF FRUITS WITH ACETYLENE

#### General.

The use of acetylene for artificial colouring and ripening of fruits is not new. Although until 1928 research on the use of various gases was mainly concerned with the action of certain non-saturated hydro-carburates, especially ethylene and propylene, acetylene, which is a hydrocarbon still less saturated than the other two, had been the subject of occasional and inadequate research only. In 1924, in attempting to determine the various gaseous constituents causing the coloration of fruits, F. E. DENNY (1) noticed that commercial acetylene had a very definite action, but he also observed that if this gas were purified by treatment with ethylene dibromide and by mixture with an alcoholic solution of potash, its efficacy disappeared; R. B. HARVEY (2), of the University of Minnesota, tried in 1925 to use acetylene for ripening celery. The smell of the gas is slight in concentrations of 1 %<sub>00</sub> and even of 1 %<sub>000</sub>, such as are required for the operation. If precautions are taken to expose the vegetable to the air for a couple of hours after removal from the colouring room, no alliaceous smell or taste can be detected in celery ripened by this method. It would appear, therefore, that the action of acetylene is comparable to that of ethylene, inasmuch as it merely accelerates the process of natural ripening by stimulating the action of the enzymes normally present in the plant. Again, in 1928, HARVEY studied the action of the gas on the artificial ripening of fruits and vegetables, but merely reported that its use was not satisfactory, without describing the method employed.

A thorough study of the action of acetylene on the process of fruit ripening presented a twofold interest, however; firstly, to find out if the gas really had the same action as ethylene, and secondly, if such is the case, to find support for the hypothesis that the action of acetylene depended in some way upon the state of non-saturation of the molecule.

More complete research work has been done on this subject during the last ten years, especially in the United States, the Union of South Africa, Australia, Italy and France. Although not always in entire agreement, the results of this research work are of real interest owing to the practical results to which they have led.

Below will be found a description of the most important studies made during the last ten years in connection with the use of acetylene as an agent stimulating the colouring and ripening of fruits and vegetables.

\* \* \*

In 1928 R. H. HARTSHORN (4) submitted a study to the « Physiological Section of the Bot. Soc. Amer. », on the effects of acetylene on the ripening of bananas. His conclusions are as follows:

Acetylene treatment hastens the ripening process of entirely green fruit. This is proved by the increase in the rate at which the pulp softens and in the rate of respiration and by the rapid alteration in taste and colour. Since purified gas was used in many of these experiments, the results cannot be attributed to ammonia or other impurities in the acetylene. The principal effect of the gas appears to be a shortening of the period of least activity which occurs normally at the beginning of the ripening process and which may be considerably lengthened by unfavourable factors such as cold. It would therefore appear that the action of acetylene is similar to that of ethylene.

Experiments in the use of acetylene in the artificial ripening of fruits were undertaken in 1933-34 by the Division of Fruit and Vegetable Crops and Diseases, Bureau of Plant Industry, United States Department of Agriculture (5). The gas used was commercial acetylene containing impurity in the form of a small percentage of ethylene. Experiments were made with several varieties of oranges, grapefruits and lemons, picked from various parts of the trees; varying conditions were created in the colouring chambers, parallel tests being made in each case with ethylene. In some cases practically no change was made in the atmosphere within the chambers while in others a continuous forced circulation of air was maintained. The gas was produced by calcium carbide and introduced intermittently into some of the chambers, while in others the flow of gas was constant. In the first experiments, the proportion of acetylene in relation to air was about 1/1,000,000, a quantity which did not result in destruction of the chlorophyll of the various varieties used for the experiment, while in the case of ethylene this proportion was very efficacious; one of the first observations to be made, therefore, was that the minimum amount of acetylene required to cause the green pigment to disappear was greater than the quantity of ethylene necessary for the same purpose. It was also observed that delicate fruits, such as unripe tangerines, were not very liable to « scald » (a physiological disease in which the skin of the fruit becomes scorched), when treated with acetylene in a concentration similar to that adopted for ethylene in commercial artificial ripening, while the same fruit, when treated with ethylene, became discoloured in an unsatisfactory manner, proving that in this particular case the action of acetylene is preferable.

A study was also made of the keeping qualities of the fruits, some of which were subjected to very severe tests; on leaving the colouring chamber they were placed in a storeroom at a temperature of 21° C.; the fruit was then examined twice weekly for a month. The results are contained in the following table.

It will be seen from the table that both treatments affected the keeping quality of the fruits, but that in this respect acetylene is less harmful, more days elapsing before the fruit treated with this gas reached a given degree of deterioration than in the case of ethylene treatment; this observation is important since it allows the duration of shipment to be extended by a few days.

TABLE I. — *Percentage of spoilt fruit after treatment with ethylene and acetylene and storage at 21° C.*

In Florida the treatment is generally stopped before the chlorophyll has entirely disappeared because, once the chlorophyll begins to disappear, the process continues after the fruit has been removed from the colouring chambers.

In 1936 the «R. Stazione Chimica-Agraria Sperimentale» at Turin undertook a series of studies (6) on the artificial ripening of oranges, lemons, bananas and tomatoes with varying types of gas including chemically pure acetylene. Below are given the results obtained with this gas. The acetylene was mixed with air in the proportion of two to twenty volumes per thousand volumes of air. The gas was changed every 24 hours.

(a) BANANAS.

The proportion adopted was two volumes of gas per thousand of air; the temperature fluctuated between 11.5° C. and 12.5° C., and the humidity was between 90 and 95 per cent.

\* *Tec. e Ingh.*

After 11 days all the bananas treated had become yellow while the control fruits were still green; after 20 days the treated fruit had lost 7.7 per cent. in weight while the controls had lost 7 per cent. Chemical analysis of the fruit yielded the following results:

TABLE II. — *Chemical analysis of the pulp during treatment.*

Treatment	Acidity expressed in cc. of KOH N/10 %	Reducing sugars calculated as invert sugar %	Non-reducing sugars calculated as saccharose %	Total sugars %
Green bananas (beginning of exp.)	10.0	0.77	2.42	3.19
Yellowed bananas (11th. day):				
with acetylene . . . . .	33.7	7.65	2.37	10.02
with ethylene . . . . .	43.0	10.64	3.18	13.82
with ordinary air . . . . .	15.0	1.22	3.30	4.52
Golden yellow bananas (18th. day):				
with acetylene . . . . .	52.2	5.50	10.89	16.39
with ethylene . . . . .	55.0	6.51	10.13	16.64
with ordinary air . . . . .	47.5	5.07	10.45	15.52

These results show that acetylene not only accelerates the change in colour, but also affects the evolution of the organic acids and the formation of compound sugars. The action of acetylene, however, does not appear to be so satisfactory as that of ethylene, since it was observed that after the eleventh day the total sugar content of fruit treated with ethylene is 3.8 per cent. higher than that of acetylene treated fruit.

#### (b) TOMATOES.

Acetylene was mixed with air in the proportion of 2‰, the temperature being kept between 17 and 19° C., and the relative humidity at 90 per cent. On the twelfth day one third of the treated tomatoes had taken on a red tinge, while the control fruits were still green; on the 28th. day all the treated fruit was bright red, while the control fruit was still pale yellow. Loss of weight was 3.5 per cent. in the fruit treated with acetylene, and 5.8 per cent. in the control fruits. Analysis of the product during treatment gave the following results.

Although the difference between the various series of experiments were not great, it was observed that such differences are to be found in relation to the organic acids and compound sugars; the difference in colouring was very distinct, fruits exposed to the ordinary air were still yellow when those treated with acetylene were red.

For three years (1936-37-38) the Marrakesh Experiment Station (7) in Morocco has been studying artificial colouring, with acetylene, and has come to the following conclusions: "Artificial colouring with acetylene gas is an economic operation making it possible to put fruit on the market ten days before

TABLE III. — *Chemical analysis of the pulp during treatment.*

Treatment	Acidity expressed in cc. of KOH N/10 %	Reducing sugars calculated as invert sugar %	Non-reducing sugar calculated as saccharose %	Total sugars %
Green tomatoes (beginning of the experiment) . . . . .	41.6	1.64	0.07	1.71
Tomatoes partly red (14th day):				
with acetylene . . . . .	66.8	1.88	traces	1.88
with ethylene . . . . .	66.4	1.90	0.22	2.12
with ordinary air . . . . .	72.1	1.85	0.07	1.92
Tomatoes entirely red (28th day):				
with acetylene . . . . .	67.3	1.97	traces	1.97
with ethylene . . . . .	67.0	2.00	0.20	2.20
with ordinary air . . . . .	73.1	1.73	0.07	1.80

the usual time of commercial ripening without affecting its taste or the intrinsic varietal qualities. Success is obtained by adopting the following principles:

- (1) only fruit which is already  $\frac{1}{3}$  ripe should be picked;
- (2) picked fruit must show no trace of moisture; each drop of dew leaves a green mark;
- (3) excess of carbide harms the taste of the fruit and does not stimulate colouring;
- (4) the room must be aired three or four times a day in order to prevent the development of cryptogamic diseases.

Results of analysis of artificially coloured fruits are given below:

TABLE IV. — *Ratio of total soluble acid compounds.*

Date when sample was taken . . . .	Soluble extract %			Acidity %			Ratio of acid extract		
	20/10	30/10	20/11	20/10	30/10	20/11	20/10	30/10	20/11
Artificially coloured fruit . . . .	11.8	12.2		1.21	1.06		$\frac{9.7}{1}$	$\frac{11.5}{1}$	
Control fruit . . . . .	12	12		1.10	1.07		$\frac{10}{1}$	$\frac{11.2}{1}$	
Naturally ripened fruit . . . .			13			0.91			—

Quite recently in 1938 experiments in artificial ripening by treatment with acetylene were carried out by D. J. DREYER, Senior Fruit Inspector, of the Union of South Africa (8). The fruit treated was the Kelsey plum, of Japanese origin; these plums do not ripen readily after picking, even if the fruit has already reached the ordinary temperature. After treatment with acetylene,

however, the transformation of the fruit was so striking that a few details on the conditions under which the experiment was carried out will be of interest. The typical treatment consisted of exposing newly picked Kelsey plums to an atmosphere containing about 1 per cent. acetylene for about 24 hours at a temperature of 21° C. and then to store them in ordinary air, kept at a temperature of 21° C. After five days the fruit, which at the outset was entirely green, or else green with a reddish tinge, had become perfectly ripe; the plums were entirely red in colour and were sweet and pleasant in flavour. The importance of the treatment lies mainly in the regularity with which good ripening was obtained, showing a definite contrast with the irregular ripening of the untreated fruit; in fact, five days after treatment, only 11 per cent. of the control fruits showed normal ripening and 13 per cent. after 9 days; after the fifteenth day the untreated fruit which had not ripened withered. The variation in acidity and sugar content of the fruits ripened by treatment with acetylene appears to be normal, as may be seen from the following table:

TABLE V. — *Variation in acidity and sugar content of Kelsey plums treated with acetylene.*

Treatment	Solid elements in solution %	Malic acid %	Ratio between solid elements in solution and acidity
Unripe fruit . . . . .	15.2	0.91	16.7
Treated fruit . . . . .	14.2	0.15	92.8
Naturally ripened fruit . . . . .	16.1	0.14	111.8

#### Action of acetylene; advantages and disadvantages as compared with ethylene.

On the basis of recent experiments described above, it may be affirmed that the effects of acetylene are similar to those of ethylene; one thing is certain; *i. e.*, that this gas has a selective action on the chlorophyll which is transformed into a colourless pigment allowing carotin and other pigments (Lycopin) characteristic of ripe fruit to make their appearance.

This alteration in colour is accompanied by various internal transformations: hydrolysis of the starchy matter, softening of the cellular walls, increase in rate of respiration, reduction of tannins, and an increase in the acidity of certain fruits (tomatoes). Acetylene treatment has a tendency to shorten the period of low activity which is generally to be observed at the outset of the ripening process and which is often considerably prolonged by unfavourable conditions, such as frost. A comparison of the two methods reveals certain differences: when acetylene is introduced into the colouring chambers in the same proportion as ethylene, the green pigment of the fruit does not disappear so rapidly and, in especially difficult cases, the disappearance is very much slower. If identical results are to be obtained, the proportion of acetylene must be much greater. These differences are illustrated in the table given below.

TABLE VI. — *Percentage of complete colouring in certain fruits before and after treatment with acetylene and ethylene (5).*

Fruit	Acetylene		Ethylene	
	Before	After	Before	After
Oranges . . . . .	64	83	63	88
Grapefruits . . . . .	48	89	48	90
« Temple » oranges . . . . .	38	72	39	78

Both treatments injure the keeping qualities of fruits but acetylene affects them to a lesser degree and while the advantages and disadvantages of the two gases are more or less evenly balanced from the standpoint of their effects upon the fruit, the same cannot be said from the economic and practical aspects; acetylene is less expensive than ethylene and can be produced by the grower himself from calcium carbide, although it can also be obtained commercially in metal containers; the plant for the production of gas from calcium carbide is simpler and cheaper as regulators are not required.

One of the disadvantages of acetylene, however, is its disagreeable odour which, according to certain workers, (HARVEY (3), RAIMUND H. MARLOTH (9), imparts a disagreeable flavour to the fruit treated; it may even be toxic and may also be the cause of headache among the staff employed in the colouring chambers. Some authors, including RAIMUND H. MARLOTH, of the Horticultural Research Station at Nelspruit in the Union of South Africa, even advise against its use for the following reasons:

(a) mixed with air it is more dangerous than ethylene because of its greater tendency to explode;

(b) although cheaper, acetylene is not economical, since at least three times as much acetylene as ethylene is required to colour the same amount of fruit;

(c) finally, the above-mentioned author, supported by DENNY (1) attributes the efficacy of acetylene solely to the amount of impurity in the gas and, since the content of impurities may be very variable, it is impossible to know whether the gas introduced into the chambers will be too active or not active enough.

These objections are denied by others; though there is slightly more danger of explosion with acetylene, still in the proportions in which this gas is used, this danger is not very serious, unless a flame is brought near the point at which the gas is introduced into the colouring chamber.

Suitable concentrations vary considerably with the different varieties of fruits. M. D. J. DREYER (8), experimenting with Kelsey plums, obtained good results with a high concentration: 1 per cent. maintained for 24 hours, but this would appear to be an exceptional case. As a general rule, concentrations are much weaker: from 1‰ to 1‰ to blanch celery, 2‰ for colouring oranges, lemons and tomatoes; these proportions are comparable to those used in the case of ethylene treatment.

Differences in action showing the superiority of ethylene are only observed in the case of very weak concentrations; at a concentration of about one million volumes, acetylene is not yet active, whereas ethylene is already sufficiently active to cause the chlorophyll to disappear from certain fruits (oranges, grapefruits, etc.).

The statement that the action of the gas is solely due to the proportion of impurities in it is definitely denied by some research workers: R. H. HARTSHORN (4), when studying the effects of acetylene on the ripening of bananas in 1931, found that these effects were really due to the acetylene and not to the ammonia or other impurities often contained in this gas, since it had been purified prior to use; this purification also removed every trace of ethylene. More recently, in 1936, A. ZAVANAJU, of the « R. Stazione Chimica-Agraria Sperimentale » at Turin, carried out his experiments with pure acetylene prepared in the laboratory from calcium carbide and brought to the point of chemical purity. As we have seen, the results of these experiments establish clearly that pure acetylene is efficacious in artificial ripening. There are therefore two opposing theories, on the one hand, that propounded by R. H. MARLOTH and F. E. DENNY, according to whom the impurities contained in the gas are alone responsible for the increase in the rate of ripening; on the other, the theory of R. H. HARTSHORN and A. ZAVANAJU, who state that it is the acetylene alone which is efficacious. Further study of the question is necessary to decide this controversy. In any case, one thing is certain, *i. e.*, that acetylene as manufactured from calcium carbide or as purchased commercially in metal containers, increases the ripening rate of fruits; this is the important point for the user.

The negative results obtained with pure acetylene by DENNY in 1924 and by R. H. MARLOTH in 1935 may have been due to other causes, in particular, to a lack of potash. According to WLODECK and BONING (10), juices, squeezed from fruits picked from plants suffering from a lack of potash, show a higher pH and are therefore more alkaline than those of fruits picked from normally nourished plants; another phenomenon is that these plants are especially rich in chlorophyll which is, however, not found in its usual form, but attached to particles of albumen, especially on the surface. REMY (11) has shown how the chlorophyll in plants lacking in potash does not dissolve in alcohol as easily as in the case of normal plants. If fruit from plants poor in potash is treated with acetylene (e. g. tomatoes), the chlorophyll is not entirely destroyed, but is still present in part and prevents the appearance of the typical red colour. The reason must be either that these fruits contain a relatively large quantity of chlorophyll, or that the composition of this chlorophyll is different from the normal. The pigment exists in those parts of the fruit containing least potash. These are the oldest parts of the fruit and include the regions surrounding the peduncle, whence the largest quantities of potash are directed towards the newer tissues. The observation that colouring is less uniform in certain fruits, and the fact that sometimes parts of perfectly ripe fruit remain green, support this thesis. It is thus probable that certain parts remain green as a direct consequence of lack of potash.

### Material and Methods employed in the treatment.

The same material is used in acetylene treatment as in the case of ethylene treatment: a room for the production of the gas, colouring chambers, etc.; the gas can also be produced in the colouring chamber; one pound of calcium carbide produces about 145 lb. of gas. The exact quantity of calcium carbide to be used is determined by the size of the room, its water-tightness and the ratio of volumes of gas and air with which it is desired to treat the fruit; this ratio is variable, but the average appears to be, roughly speaking, between 2 and 4 per cent.; thus, for the artificial colouring of oranges, 28 grams of calcium carbide per 2000 litres of air are more than sufficient. The following table indicates the proportions which have given the best results in orange colouring in Queensland (12):

TABLE VII. — *Optimum proportions of calcium carbide for the artificial colouring of oranges.*

Cubic contents of chambers in litres	Number of one-bushel cases (36 litres)	Volume of air after introduction of gas (in litres)	Quantity of calcium carbide in grams
5,400	40	4,050	56
5,400	20	4,725	65
5,400	10	5,062	70

The simplest method of production consists in pouring the calcium carbide directly into a bucket of water placed in the colouring chamber; by this method, however, the gas necessary for filling the chamber is obtained in a single operation, and it seems better to slake the carbide slowly, and gradually. As in the case of ethylene treatment, the rooms should be aired at least once every 24 hours.

The Marrakesh Experiment Station (7) has worked out a very simple method of artificial colouring, which will be of interest to fruit growers. It has been used for citrus fruits, but could be used equally well for other fruits, by altering the gas concentration and the duration of treatment when necessary.

"The fruit is picked when every trace of dew has disappeared. There is a risk of deterioration during treatment if the fruit is moist, and each drop of dew leaves a green spot on the ripe fruit. The fruit is placed on shelves in the colouring room, measuring be 2 m.  $\times$  3 m.  $\times$  2 m.; these dimensions vary with the amount of fruit to be treated. The floor should be sprinkled with water in order to maintain the relative humidity between 90 and 95 per cent. to prevent the fruit from withering, as acetylene gas dries the atmosphere.

"The carbide is placed in lamps from which the burners have been removed to facilitate the flow of gas. The quantity of carbide is 25 grams per cubic metre; too much carbide may give the fruit a very disagreeable alliaceous flavour without in any way accelerating the ripening. To avoid mould, which might result from the humidity of the atmosphere, the rooms should be aired every four or five hours by opening the door for half an hour to change the air; the lamps should then be refilled and the door closed".

\* \* \*

A rather specialized use of acetylene in fruit-growing, which may, however, be considered with what has been said above since the purpose is the same, is that followed in the cultivation of pineapples, especially in Queensland and the Hawaiian Islands. It had long been known that early flowering of pineapples could be stimulated by exposing the plants to the action of certain gases for 12 or 24 hours. Research work carried out in Queensland (13) shows that plants which would normally flower in February and March, when treated with acetylene, flower in October and November, and that consequently the fruit ripens by March, April and May, *i. e.*, at the time when climatic conditions are most favourable in that region. The method consists of spraying the plants with acetylene saturated water between September and March. Flowering is thus stimulated and takes place from 7 to 8 weeks after treatment.

It would be interesting to study whether this method, by which it is possible to ripen fruit at a better season and to space production, could not be adapted to other varieties of fruit.

### Conclusion.

Although acetylene gas has not been used as long as ethylene, and although experiments with the former gas have so far been made on a very limited numbers of fruits at different stages of ripening, these experiments suffice to justify its introduction into commercial practice for certain fruits. Before recommending this treatment for general use on the same basis as ethylene, however, it would be advisable to continue research work on other varieties of fruits.

## SOME LONCHOCARPUS SPECIES, ROTENONE YIELDING PLANTS OF SOUTH AMERICA (\*)

### I. — Botany — Cultivation — Producing Countries.

#### INTRODUCTION.

For a long time past, native inhabitants of tropical regions have utilized as fish poisons the juice of certain plants that have toxic properties. In the Amazon region, for example, and generally in Central and South America, the poisoning of small streams is still commonly practised, by means of plants, trees, shrubs, lianas, grasses, etc., belonging to different natural families. The toxic properties of these plants are due to various substances and in particular to alkaloids, glucosides, etc. The active principle of one of these plants (*Derris*), which yields a very strong fish poison, was isolated for the first time in Japan, and the name of rotenone finally given to it. Later, in 1929, CLARK isolated the same principle from the roots of different species of *Lonchocarpus* obtained from Central and South America. Rotenone soon acquired great importance as an agricultural insecticide and this gave rise to a careful survey of the plant species capable of supplying this substance in adequate quantities. In 1933 some Americans settled in Brazil to survey the extent of plants supplying rotenone in the forests of the Amazon. The purpose of this article is to report briefly on the results obtained up to now in regard to American rotenone-yielding plants.

#### BOTANICAL SPECIES.

The genus *Lonchocarpus* is abundantly represented in Central America, in Mexico, in the tropical regions of South America and in the West Indies. It is also found in South Africa and in Equatorial Africa, as well as in Madagascar and in Australia. The majority of the species found in Central America are however not found elsewhere.

All these fish-poisoning or fish-stupefying are known by the native populations of the countries of South America under various names. For example, these species are known in Peru under the generic term of "cubé", in Brazil as "timbó", in British Guiana, as "haiari", in Dutch Guiana as "nekoe", in French Guiana as "nicou" and in all the countries of South America as "barbasco". These same terms may further be applied to different fish-

---

(\*) This article is a sequel to and supplements that on Cultivation of *Derris* in the Far East (see this *Bulletin*, No. 1, January 1937, pp. 1-12). The Section of Tropical Agriculture of the International Institute of Agriculture, in view of the increasing importance of the cultivation of insecticide plants yielding rotenone, which are all tropical crops, has decided to prepare a general survey of the problems connected with this new production and of the results already obtained.

poisoning plants in different countries. Thus the term "cubé", which in Peru is used to designate only plants belonging to the genus *Lonchocarpus*, is used in other countries to designate fish-poisoning plants belonging to another genus of the family *Leguminosae* (e. g., *Tephrosia*) or even belonging to another family. Hence it is essential to define these terms as precisely as possible. For this purpose special use will be made of results published by KILLIP and SMITH and by ROARK, as these writers after patient investigation have been able to determine beyond dispute the species and varieties indicated under a given native name. It is impossible to give here the full list drawn up by these investigators; a brief note will be given only on the principal plants.

(a) BARBASCO. — This is the term generally employed in the Spanish speaking countries to designate fish-poisoning plants. The word is derived, it appears, from *Verbascum*, the plant genus formerly utilised in Spain and in other European countries for stupefying or poisoning fish. According to KILLIP and SMITH, in Central and South America this term is especially applied to two species of *Lonchocarpus*: viz., *L. guaricensis* and *L. nicou*.

(b) CUBÉ. — The term cubé is a Peruvian word which, in Peru, designates all species of *Lonchocarpus* which are ichthyotoxic and in particular *Lonchocarpus nicou*; in other regions, it designates all plants used for poisoning fish.

(c) HAIARI. — The term haiari is employed in British Guiana for designating certain species of *Lonchocarpus*, including *L. nicou*. Various kinds of haiari are distinguished by the natives, viz., the "white haiari", the "black", the "red", the "bastard haiari" and the "haiar-balli". According to KILLIP and SMITH, the two first correspond to *L. nicou* and the two last to *L. densiflorus*. In addition *L. rariflorus* is regarded as a variety of "black haiari"; it is known more often under the name of "Faia-fai-noroko". It has been noted besides that a variety recently gathered along the river Berbice and formerly considered as being "black haiari" is in fact different, and it is possible that it corresponds to *L. Chrysophyllus*.

(d) NEKOE. — This term is used in Dutch Guiana to designate especially *L. nicou* and *L. Chrysophyllus*. The nekoes are also known in Dutch Guiana under the name of tienghihoede, tetei, touw and hajari.

(e) NICOU. — This term is used in French Guiana, and in the French Colonies in general, to designate *L. nicou*. This species is also known as in Guiana under the name of intoxicating wood.

(f) TIMBÓ. — The greater part of the fish poisoning species are known under the name of timbó in Brazil. The classification still remains uncertain; the principal Brazilian timbós will only be mentioned.

1. "Timbó legitimo" or "macaquinho" which seems really to be the *Robinia nicou* of AUBLET, or *L. nicou*. This species is found in Peru and also on the Lower Amazon, always close to inhabited sites and not in the completely wild state.

2. "Timbó vermelho" or "Timbó urucú" corresponding to *L. urucú*.

The designation of *T. urucú* is used especially in the Lower Amazon (Gurupá) region as well as in the Rio Xingu; that of *T. vermelho* is used in the regions lying between the Amazon and the Pará.

In addition to these two kinds of timbós, which are the richest in rotenone, the following may be mentioned: the «timbó venenoso» of Pará (*L. floribundus*), which is found in all the Amazon region and is said to contain a toxic glucoside, timboine, the «Timbó grande» or «common Timbó» found especially in the region of the Rio Tapajoz; the «Timbó páo», of the region of the Rio Acará.

All these timbós have a more or less high rotenone content, they all belong to the genus *Lonchocarpus*, they are most often found in the form of lianas which may be confused with other lianas which have no toxic qualities. Finally the confusion is increased by the fact that this same name of timbó is given to a number of other plants belonging to different genera and even to different families. A detailed study of all these rotenone yielding plants in the Amazon region has still to be made.

#### BOTANICAL DESCRIPTION OF CERTAIN LONCHOCARPUS SPECIES.

The first botanical description of a «timbó» belonging to the genus *Lonchocarpus* was made by F. AUBLET in 1775. This botanist gave the name of *Robinia nicou* to the plant he described; later this name was changed to *Lonchocarpus nicou* (Aubl.) Benth. Lately the botanist E. P. KILLIP of Washington has described two new species of timbós which are respectively *Lonchocarpus urucú* and *L. floribundus*. Finally the latest surveys made in the different parts of the Basin of the Amazon have proved that at least six species of *Lonchocarpus* must exist with roots of more or less high rotenone content. The identification of these species is, as already noted, very difficult, as certain species much resemble some plants of the genus *Derris*. Guidance in botanical investigations may however be of gained from the important fact that *Lonchocarpus* spp. are not met with in the primary virgin forests but only near dwellings or on the site of former plantations or long deserted crops. From a purely practical point of view, the distinctive characteristics of the different species can be quickly ascertained by an examination of the habit of growth of the plant, leaves, flowers, branches and roots.

The descriptions of the principal species are as follows:

(a) *Lonchocarpus nicou* (Aubl.) Benth.

According to KILLIP and SMITH, this is a bush or small tree which may attain the height of 3 metres; the diameter of the principal stem is from 4 to 8 cm.; the branches spring from near the top of the stem and the plant may climb over other plants in the neighbourhood up to a height of some ten metres. The leaves are alternate, compound imparipinnate, the base of the main leaf stalk and the petioles are thickened; the opposed leaflets (from 2 to 4 pairs, usually 3) are oblong, occasionally oblong lanceolate or oblong oblanceolate, from 12 to 25 cm. long and from 4 to 10 cm. broad; they are acuminate at the apex, subacute or sub-rotund at the base, entire, coriaceous (leathery) or

sub-coriaceous; their upper surface is dark green, somewhat glossy and very glabrous, the underside is paler, sometimes glaucous, usually covered with thick reddish or golden brown hairs; the ribbing is pennate, the central rib is sometimes depressed on the upper side and prominent on the lower; the lateral ribs, from 7 to 10 on each side, point up the leaf and turn over towards the margin.

AUBLET describes the flower as follows: *Calix; perianthium monophyllum, quinquedentatum. Corolla papilionacea, purpurea, vexillo amplo, erecto. Pericarpium; legumen longum acutum, gibbosum, glabrum, rufescens, uniloculare, bivalve. Semina tria aut quatuor, subrotunda, compressa, marginibus valvarum affixa.*

KILLIP and SMITH in their description do not speak of the flowers or of the fruit, probably because the plant flowers only after many years of growth and the plants examined by them were generally not more than 6 or 7 years old.

(b) *Lonchocarpus Urucú* Killip.

The *Lonchocarpus Urucú* is found under the form of a great liana, almost of bush habit. The underside of the leaves and of the flowers is covered with rust-coloured hairs; the leaves are compound, formed of from 3 to 4 pairs of leaflets, opposite and with a terminal leaflet; the leaflets are oblong or elliptical, rounded at the base and ending abruptly in a short point; their length is from 7 to 17 cm. and the breadth from 3.5 to 8 cm.; the upper surface of the leaves is glabrous. Every part of the blade of the leaflets is traversed by 8 to 10 ribs. The inflorescence is axillar, lateral, and consists of branched panicles, compact; the flowers are small, grouped, and red in colour, 13 by 5.5 mm. The fruits are flattened oblong pods, from 4.5 to 8.5 cm. long by 2.5 to 3 cm. broad.

(c) *Lonchocarpus floribundus* (Benth).

*Lonchocarpus floribundus* is a large liana with a large number of bright red flowers. The branching shoots, the leaf stalks and the inflorescences are glabrous; the compound leaves have long leaf stalks, and 2 or 3 pairs of opposed leaflets with or without an odd terminal leaflet; the leaflets are petiolate, oval or elliptical the odd leaflet is ob-oval; all the leaflets end in a blunted point or mucronate apex.

The leaves are glabrous on the upper side and of a somewhat olive colour, on the under side they are covered with dark or rust coloured hairs; the length is 5.5 to 12 cm. and breadth 3 to 7 cm. The inflorescence is long, lateral and terminal, never compact, branched: the flowers are grouped, stalked, small (1 cm. by 6 mm.), calyx in form of standard, with hairy coat; the fruit is a smooth, flattened pod, 6 to 7 cm. long by 2 broad; it contains one seed only.

GEOGRAPHICAL DISTRIBUTION.

The species of *Lonchocarpus* having insecticide properties are chiefly found in the Amazon basin and at the base of the first foothills of the surrounding mountains, in a region, that is, extending from 3° Lat. N. to 15° Lat. S. This

region is bordered on the west by the Andes and plentifully watered by innumerable streams.

In this zone two very different topographical regions are to be distinguished, namely:

- (a) the "varzeas" or plains periodically inundated by floods;
- (b) the "terra firma" which lies above the highest level reached by the floods.

Actually the whole of the Amazon basin is at a low altitude except for certain areas which rise to 150 or 200 metres. Even the "terra firma" areas rarely exceed an altitude of some thirty metres above the flooded plain. It is mainly on the well drained portions of these lands, and of those lying at the base of the foothills of the ranges surrounding the Basin, that species of *Lonchocarpus* are found in the wild state.

According to observations made by explorers, *Lonchocarpus nicou* is found in Peru in a zone situated between 12° 50' Lat. S. and the Equator, in mountainous or tropical areas including the Departments of Loreto, San Martín, Amazonas, Junín, Ayacucho, Cusco, Madre de Dios and Apurímac. KILLIP and SMITH also mention the existence of cubé in the department of Huancayo; WEBERBAUR found this species in the region of Moyobamba, in the valley of Monzón, near Cachicoto and in other localities of the eastern part of Peru. In 1922 W. J. DENNIS found cubé plants on the other side of the Andes, in a mountainous region. Four well marked zones may thus be established in Peru where cubé is to be found either cultivated or growing in forests, as follows:

(a) The region of Madre de Dios. In this region cubé is found at Maldonado at an altitude of 225 metres above the level of the sea;

(b) The region of Ucayali. This region is well watered; cubé is found mainly in the locality of Aina in the mountains of Huanta, in the localities of Pedregal, Santa Ana (1081 metres above sea level) and of Quelluno (695 metres) in the region of Urubamba; of Cahumapana on the Pichis river; of Pucallpa on the Bajo Ucayali; in the valley of the Aguaytia (in the wild state) and finally at Contamana (134 metres), and along the streams Sarayacu and Santa Catalina (in the cultivated state).

(c) The region of Huallaga. Plantations of cubé are found in the Chinchao mountains and in the localities of Monzón and of Cachicoto, at an altitude of 617 metres. They are also found at Tocache (512 metres) on the stream of the same name, at Pachiza and at Saposoa (308 metres).

In the valley of the Mayo, cubé is found in the neighbourhood of Moyobamba (866 metres) and of Tarapoto (374 metres). On the Huallaga cubé plants are found at Chasuta (260 metres) and at Yurimaguas (170 metres); the plant is also found at Santa Cruz and at Lagunas.

(d) The region of Marañón. The Marañón is a river which rises in the Cordillera of Huaihash, between the departments of Huánuco and Junín. Cubé is found on the right bank of the river at Jeberos and at San Antonio. On the left bank plantations are found at Jaén (740 metres), at Puerto Pardo, at Barranca and on the Pastaza.

It will be seen from this brief survey that cubé is a plant which occurs in the wild state in an extensive zone of Peru and in the cultivated state in many localities. The principal centres for supply of the roots are situated in the region of Huanta in the central part of Peru.

In Brazil, the different kinds of timbó are nowhere cultivated; all that is done is to utilise those which grow wild in the forest. ROARK considers that the different kinds of timbó in Brazil are met with in the regions situated at an altitude below 900 metres. The larger proportion of the *Lonchocarpus* roots exported from Brazil come from the States of Pará and Amazonas in the North.

#### CLIMATE.

In comparison with many tropical countries, the annual rainfall in the Amazon Basin cannot be considered high. The torrential downpours common in many Equatorial regions are quite rare. The heaviest annual precipitations fall on the western edge of the Basin in Peru and Bolivia. According to WILLE, *Lonchocarpus* spp. require fairly heavy rain preferably evenly throughout the year. In the region of the Montaña, the rainy season lasts from October to May and is at its height from January to April; the lighter rains are in July and August. During the wet season, rain falls regularly during the night, and at daybreak the ground is covered with mist, which as a rule quickly disperses and the sun shines till 2 or 3 p.m., when the violent downpours begin again. In this region the annual precipitation always exceeds 80 inches (2,032 mm.).

Very heavy and well distributed rains occur also in the neighbourhood of Iquitos (Peru), and annual precipitations have been noted there to a depth of 2,500 mm. The rainy period also lasts from October to May.

In the State of Pará, Brazil, the rainfall is approximately the same as that of the Peruvian regions just described. It would appear, however, that the rains are more seasonal and somewhat less in quantity..

From the above summary of weather conditions it may be gathered that the rainfall requirements of *Lonchocarpus* vary somewhat according to species, but that in any case these plants require a hot and wet climate.

#### SOILS.

Examining the ground where *Lonchocarpus* grows wild, it is found that it adapts itself freely to any kind of soil. It however prefers light, sandy, permeable soils, such as occur along the streams of the Mojitana in Peru. Root development and gathering appear to be made easier by a permeable soil. Well washed and gravelly land is unsuitable. The general topography of the ground is also important; plantations should not be made on the banks of streams which periodically overflow.

As regards the chemical composition of the soil, recent research shows that *Lonchocarpus* does best on acid soils rich in humus.

## CULTIVATION.

In the principal producing countries, *Lonchocarpus* spp. are grown on plantations of varying size, in preference close to dwellings. KILLIP and SMITH who visited Peru a short time before the powder of *Lonchocarpus* became an article of trade, stated that the plantations were of very varying size, from small crops of 25 to 100 plants enough to cover the needs of one family, to large plantations of more than 10,000 plants enough to meet the requirements of the whole neighbourhood.

(a) *Methods of propagation.* — Propagation by cuttings is generally adopted in all the countries where cultivation is practised. The native method is simply that of burying in the soil to the depth of some ten centimetres a piece of stem about thirty centimetres long. La Molina Experiment Station (Peru) recommends the adoption of the following method for establishing a new plantation:

“Cuttings should be taken on the main stem, as near as possible to the root collar and if possible with traces of attached roots. Cuttings should be about 30 cm. long, with two or three nodes; they should be placed in the ground at an angle of 45°, leaving one node out of the ground. Plants should be 1.50 m. apart in every direction. In Peru cuttings should be made in September or October. The growth is rapid; as a rule at the end of the first year the height attained is one metre, at the end of 2 years, 1.80 m. and at three years, 2.50 m. As gathering cannot take place till the end of 3 or 4 years, the cubé plants are planted in association with yuccask, pineapples or rice.”

It is of interest to note an attempt at layering *Lonchocarpus nicoi* which was entirely successful. The trial was made in the Botanic Garden of Los Baños, Philippines Is.; the object was to effect a rapid multiplication of young nursery plants of *Lonchocarpus* which had been sent from Peru and were not growing well. The procedure was as follows: the branches chosen were stripped of their bark at a convenient point to a length of about 2 cm. The cambium layer thus exposed was scratched with a pruning knife to prevent cicatrization of the wound during the period of the formation of the callus. A month later when the callus was well formed, the scar was wrapped round with a wad of coir fibre containing equal parts of garden soil and horse manure: by a suitable device, the humidity most favourable to the formation of roots was maintained at this point. At the end of a month and a half some roots could be observed, which a week afterwards were so far developed that the branch was severed, and was then planted in a pot, leaving the wad of coir fibre adhering. Some weeks later strong and healthy rooting took place.

This experiment, made quite recently (in 1937), shows that propagation of cubé plants can be easily obtained by layering, whenever there is not enough material for cuttings to be taken.

(b) *Shading.* — The influence of shade plants on the growth of *Lonchocarpus* spp. is not yet definitely known. Many writers maintain them to be shade-loving plants; the natural stands are found in thickets in the forests, in deserted and overgrown clearings, and less often in dense forest, usually near the edge.

Cultivated species of *Lonchocarpus* usually grow in open places. The plant being peculiarly sensitive to climatic changes, especially when young, it is advisable to plant it in association with other crops as, for example, cassava. Trials have shown that cubé crops grows better as a mixed than as a single crop.

(c) *Cultivation*. — The elimination of weeds is one of the first difficulties encountered in the growing of *Lonchocarpus*. Weeds can be kept under by planting intercalary crops, and this is a further reason for not growing cubé as a single crop.

(d) *Gathering*. — The roots are gathered at the end of the second year or in the course of the third or fourth years. Lifting of the roots may be done at any time of the year, but by preference when it is not raining, as the work is then easier and the roots taken up are cleaner. The rotenone content of the roots increases with the age up to about the fifth year.

(e) *Yields*. — Few exact figures are available as a basis for estimation of yields. KILLIP and SMITH estimate that the average weight of the roots of a plant two years old is about one and a half kg. in the fresh state. On drying, the root loses about 42 per cent. of its weight. WILLE, moreover, considers that when the roots are gathered in the course of the third or fourth year, about 2 kg. of fresh material can be obtained per plant. Naturally the root development depends on the richness of the soil; on sandy soils the roots may attain a length of 1.5 metres. Writers are not in agreement on the density of plantations. KILLIP and SMITH reckon that from 4200 to 4400 plants per hectare may be grown. The Peruvian writers regard this as an exaggerated estimate and consider that not more than from 2200 to 2400 plants should be reckoned to the hectare. Taking this latter figure and calculating 2 kg. of roots per plant, a production of from 4400 to 4800 kg. of fresh roots per hectare is reached, yielding some 2,000 kg. of dried roots.

In Brazil, much higher yields are reported; actually according to information supplied to the Imperial Institute in London by the Commercial Attaché of Rio de Janeiro, the production of fresh roots of timbó plants three and a half years old was as much as 17.5 m. tons per ha. It will be seen that it is difficult at present to deduce a precise average from the facts known up to now.

#### DISEASES AND PETS.

Various insects and fungi are mentioned in the world bibliography on the subject as attacking cultivated or wild cubé plants. Mention will here be made only of *Aspidiotus articulatus* which, according to SEABRA, attacks the leaves and branches of a species of *Lonchocarpus*, and *Metoposoma porosum* Marshal, which bores the trunks of other Brazilian species of *Lonchocarpus*. Other pest that attack these plants in Brazil are *Diorchidium manaosense* P. Henn., *Endothiella lonchocarpicola* (P. Henne.) Theiss. and Syd., *Ophiodothella atromaculans* (P. Henn.) v. Hoehn. *Ravenelia lonchocarpi* Laght and Diet, and *Ravenelia bakerians* Syd.

*Lonchocarpus nicou* plants growing wild or cultivated in Peru are not, it seems, attacked either by insects or by fungi.

## SURVEY OF THE EXPLOITATION OF LONCHOCARPUS SPP. IN THE PRINCIPAL PRODUCING COUNTRIES.

(a) *Peru*. — At present 90 per cent. of the world production of cubé roots come from the eastern part of Peru. The principal port for the export of the product is Iquitos on the Amazon. All the preceding notes on the cultivation are based on information from Peru and apply especially to that country; further remarks will be limited to some notes on the times for sowing and gathering of cubé in the different Peruvian districts.

TABLE I. — *Times of sowing and of gathering of Cubé in the various departments of Peru.*

(according to J. E. WILLE, J. Alcides OCAMPO, A. WEBERBAUER and D. SCHOFELD).

The first scientific cultivation trials were undertaken towards 1934 at the La Molina Experiment Station; then, in 1935, at the Loreto Experiment Station. These trials showed that the best species was *Lonchocarpus nicou*, the rotenone content of the roots varying from 5 to 15 per cent., while that of the roots of other species is always lower. The increase in rotenone content appears to be in relation with the quality of the soil; in the course of experiments, a larger increase has been noted when the plants are growing in silico-clayey soils and

when the climate is not too humid. At the La Molina Agricultural Station, it has been observed also that plants sown as an intercalary crop do better than those grown without shading.

At the time of gathering, the roots have a water content which depends on the season and on the nature of the soil. In many cases the approximate limits of this moisture, calculated *a priori* by some observers, may be exceeded. Thus observation at the La Molina Experiment Station has shown that a root taken from a plant one and a half years old weighed a kilogramme at the time of gathering and only 575 grammes after it had been kept for 15 days in the open air in the shade. Other experiments have shown a much smaller decrease in weight, such as 500 grammes for an initial weight of 1800 grammes. In any case, the conclusion is that buyers of fresh roots will have to count on a loss of some 50 per cent. during drying.

So as to obviate all difficulties in the estimation of this loss, sales of roots in the dried state only are advised by the La Molina Experiment Station.

The Station also advises growers to utilize special stoves to secure adequate drying. For marketing, roots should be selected and graded according to their rotenone content; the low prices up to now paid are entirely due to the want of homogeneity in the material offered.

(b) *Brazil.*

The Brazilian timbós are especially abundant in the Pará region. The working of these is of the most primitive type, as these plants are seldom cultivated in the proper sense of the term. All that is done is to cut the young roots of the lianas on the natural stands and to transport them to the mills (factories).

The best species found is Timbó macaquinho (*Lonchocarpus nicou*). In experiments propagation by cuttings of this species has been found to be very successful and growth is rapid. The quantity of roots obtained is not so great as with other species, as for example the timbó urucú, but as the plants take less space, the number of stocks to the hectare can be increased so as to obtain a very satisfactory yield. The rotenone content of the roots is at a maximum in a plant from 2 to 2 ½ years old, when it is an erect shrub with no need of a support.

The roots of timbó macaquinho contain 6 to 12 per cent. of rotenone, a much higher content than the roots of *Derris elliptica*.

Cultivation trials have been made with other species, such as timbó vermelho (*L. Urucú*), timbó grande, etc., the rotenone content of the roots varying from 3 to 5.5 per cent.

All these trials show that to obtain a regular rotenone yield, the working of species dispersed in the forests is not enough, but it is essential to undertake systematic cultivation on a large scale. As the species for cultivation, timbó macaquinho should be chosen, not only because the rotenone content of the roots is very high, but also because the roots do not contain resins or colouring substances, and hence the process of extraction is simplified and losses avoided.

The roots after gathering are chopped into thin slices while still fresh, then placed in the stove and reduced to a very fine powder.

This treatment is mainly carried out at Belem (Brazil), where there are already half a dozen specialised factories.

Four commercial grades of timbós have been fixed by the General Department of Agriculture:

Grade 1: Roots of timbó macaquinho.

Grade 2: Roots of species of the type of timbó urucú.

Grade 3: Roots of the two species above mentioned.

Grade 4: Roots of various species of timbós.

Each grade includes three commercial types, *viz.*:

Grades 1 and 2. — *Good*: 90 per cent. of new roots belonging to the two classes, 3.5 cm. or more thick, in good preservation and clean. *Medium*: 65 per cent. of new roots in good preservation and clean, from 12 to 25 per cent. of mouldy and earth stained roots. — *Inferior*: 50 per cent. of new roots, in good preservation and clean, from 25 to 50 per cent. of mouldy earth-stained roots.

Grade 3. — *Good*: 50 per cent. of urucú and 50 per cent. of macaquinho: new roots, 3.5 cm. thick, in good preservation and clean. — *Medium*: 70 per cent. of urucú and 30 per cent. of macaquinho, new roots including 12 to 25 per cent. mouldy and earthstained. — *Inferior*: 80 per cent. of urucú and 20 per cent. of macaquinho, new roots 3.5 cm. thick including 25 to 50 per cent. of mouldy or eart stained roots.

Grade 4. — *Good*.: up to 50 per cent. of macaquinho, new roots, 3.5 cm. thick, in good preservation and clean. — *Medium*: 30 per cent. of new macaquinho roots 3.5 cm. thick including from 12 to 25 per cent. mouldy and earth- stained roots. — *Inferior*: up to 25 per cent. of macaquinho, new roots, 3.5 cm. thick, including from 25 to 50 per cent. of mouldy or earth-stained roots.

(c) *British Guiana.*

Since 1929, "black" and "white haiari" have been cultivated on the experiment stations in the North-west district. At Horosoro, the plants have been grown with and without shading on lateritic soils; at the Wauna Station the same crops have grown, with and without shading, but on sandy soil. In both cases the shaded plantations consisted of secondary forest in which the undergrowth and smaller trees had been cut away. Propagation was easily effected by means of stem cuttings. It was soon clear that growth was more vigorous on sandy soil than on lateritic soil, and on shaded than on unshaded ground. At first the "black haiari" grew more slowly than the "white haiari", but at the end of three years, there was no longer any difference. The unshaded plantations were weeded during the first three or four years of growth.

Before these experiments, flowering had never been reported among the haiaris; in 1935 some plants of "white haiari" suddenly flowered on the non-shaded plantations at Wauna, and it was thus possible to identify this species as being *Lonchocarpus nicou*.

When the "black" and the "white haiari" are grown together it is easy to distinguish the two species. Actually the former has a very characteristic dark brown bark, and the leaflets tend to be a darker green than the leaflets of the other species. The hairy coat on the leaves of the "black haiari" is also thicker than with the "white haiari". Comparable leaflets belonging to these two species, grown under the same conditions, present several distinctive characteristics; on the other hand, considerable modifications with age and habitat take place in leaflets, and distinctions based on leaf characters may be a source of error. At Wauna, on the shaded plantations, spots often occur on the leaflets of the black variety which are never found on the other variety. This is a distinctive characteristic.

In the conditions of British Guiana, the growth of *Lonchocarpus* spp. is much slower than in Peru, where at the end of four years, the plants attain a height of about 5 metres. The plants grown at Wauna were only two metres high at the end of seven years. The differences observed in the habit and in the growth of *Lonchocarpus nicou* growing under the conditions of British Guiana occur also - whatever may be the cause - in the rotenone content of the roots. The wild plants gathered in the forests of British Guiana have revealed, on analysis, a rotenone content not higher than 3 per cent., which is the minimum for the root to have marketable value: the cultivated plants have shown up to now an even lower content. Investigations are at present being carried on by the Department of Agriculture on the actual insecticide value of these roots and on the means of increasing this. Preliminary work done by the Division of Chemistry of this Department show that certain modifications must be made in the ordinary methods of determination of rotenone content when haiari roots are concerned. ROBINSON announces a new method of analysis which, in his opinion, yields more correct and satisfactory results than those obtained by the usual methods. None the less, the percentage of rotenone remains extremely low.

It has been thought that the application of lime might increase the rotenone content of the roots, and experiments have been made in pots, with a view to examining this aspect of the problem.

(d) *Dutch Guiana.*

Experimental cultivation has been undertaken of "black" and of "white haiari" at Demerara. The former species is shown to have the highest rotenone content.

(e) *French Guiana.*

Wild stands of *Lonchocarpus nicou* were formerly to be found over the whole territory of the colony; it was in fact from a specimen coming from this colony that AUBLET was able to make the description of the inflorescence of *Lonchocarpus nicou*. At that time (in 1775) he had given the plant the name of *Robinia nicou*. Since then this plant seems to have gradually disappeared,

it is still however reported near the sources of the Maroni on the borders of the Itauy. Cultivation should be resumed, and this species could then undoubtedly take an important place in the economy of this colony.

(f) *Ecuador.*

According to available information, stands of *Lonchocarpus* exist in the eastern part of Ecuador. This plant is known under the name of timbó but does not enter into trade.

(g) *Nicaragua.*

A *Lonchocarpus* is found in Nicaragua, *L. latifolius*, H. B. K., known by the name of "pelljo de toro". This species occurs only in the wild state and often in localities difficult of access.

## II. — Chemistry and Technology

The only part of the *Lonchocarpus* plant having commercial value is the root; the greater proportion of the active principles are in fact in the root.

(a) PREPARATION OF THE ROOTS.

The roots freshly gathered are put to dry under hangars well ventilated so as to prevent any diminution of their toxic quality from the direct action of the sun's rays and to avoid formation of fungi under the action of rain.

Before storing the roots, their water content must be reduced to less than 14 per cent.; for this at least three weeks of exposure in the hangars at ordinary temperature is necessary. By using special stoves for the drying process, the length of the operation may be reduced to three days, and a lower moisture content of roots is obtained by this process. The drying plant used consists of a furnace equipped with a system of pipes for the circulation of hot air, by which a temperature as near to 75° C. as possible is secured, this being the optimum temperature at which roots should be dried. It has been noticed that roots subjected for several hours to a temperature of 100° C. yield a powder of darker colour than that obtained from roots treated at the surrounding temperature.

As already said, the roots may be stored as soon as their moisture content is less than 14 per cent.; for their export without risk of attack by fungi, their water content should however be less than 10 per cent. Actually a Decree was enacted in Peru (Decreto Supremo of April 4 1933, Art. 3), prohibiting the export of cubé roots containing more than 10 per cent. of water. Good quality roots on arrival in the United States contain on an average less than 6 per cent. of water.

During transport by land or sea, the roots must always be protected from sunlight and from rain; tarpaulin is used for this purpose. It is usual to re-

move the large roots from a consignment and to leave only the thinner ones, so as to increase the rotenone content of the whole; it has been observed that the larger roots contain only 2 to 3 per cent. of rotenone, while the others easily contain 8 per cent. and more.

For export it is advisable to compress the roots in bales of 100 kilograms, using bale-presses as for cotton.

It is a disadvantage to export roots whole as it is impossible to take a sample representative of the consignments and to guarantee their content in rotenone and in total extract. Moreover manufacturers receiving roots pressed into bales are obliged to sort them out before sending them to the mill.

On the other hand, if roots are exported already milled, it is possible to obtain a homogeneous and less bulky mixture of which the rotenone content and total extract can be easily determined.

#### (b) APPEARANCE OF ROOTS.

A detailed description of cubé and timbó roots is given by MM. J. and M. CHEVALIER, and the following information is taken from these writers:

1. *Cubé roots*. — The surface of these roots is ridged with longitudinal furrows. On cutting they show a slightly brown cortex, 1 mm. thick, surrounding a lighter coloured xylem with well formed vascular tissue, visible to the naked eye. The medullary rays are clearly visible; the medulla is small and centrally placed. There are very few secondary roots which leave an elliptical scar. On breaking, the whole is fibrous and a mass of hardened fibres are seen on the broken edges. If plunged into water a quantity of starch is released; the roots tinge the water yellow and give off a distinct odour. If mashed, they seem at first sweet, then taste more and more acrid.

2. *Timbó roots*. — These roots have the form of a rhizome, brownish yellow in colour, widely incurved on one side, where in the case of large roots there is a depression and with young roots there is a slight projection.

The diameter of these roots varies from 1 to 3 cm. The surface is striated by longitudinal furrows. The cortex is somewhat thick, from 2 to 3 mm.; it is light yellow and surrounds a darker xylem tending to brown. The vascular tissue of the xylem is well formed and visible to the naked eye so that the medullary rays are clearly seen. The medulla is small with portions extending to the periphery. The position of the medulla on the periphery varies where a root of any size is inserted on the rhizome, forming a kind of node. This peripheral displacement of the medulla is absolutely characteristic, and imparts to the medullary rays a quite special characteristic arrangement. The secondary roots are few in number and leave circular scars forming small protuberances on the cortex. On breaking, the whole is fibrous. The roots plunged into water release starch in abundance; they tinge the water yellow and give off a very distinctive odour. If mashed the roots taste at first mucilaginous and sweet, then they become more and more acrid and leave a lasting sensations of pricking in the throat.

(c) ANATOMICAL CHARACTERISTICS.

The anatomical characteristics of the roots of cubé and of timbó are nearly comparable. In the roots of timbó however the hardened fibres are massed together rather than in bundles as in the cubé roots.

(d) LOCALIZATION OF ROTENONE IN THE ROOTS OF CUBE AND OF TIMBÓ.

In their comprehensive study of the roots of cubé and of timbó, MM. J. and Michel CHEVALIER, in addition to determining the anatomical characters and the external appearance, tried also to localize the rotenone with exactness. In order to identify the position of the rotenone, they had to make use of its solubility in chloroform. Localization was first effected on a cut portion, then this was plunged into chloroform for a quarter of an hour or a half hour, when the traces previously observed disappeared. The place occupied by the rotenone could thus be determined by a simple comparison.

These investigations have shown that in the roots of cubé and of timbó the rotenone is localised in the same regions and has a similar appearance. It is found in the cortical parenchyma, especially below the cork layer and where the medullary rays project, in the rays themselves. in the parenchyma of the cellulosic xylem and in the parenchyma of the medulla. The cells in which rotenone occurs are thick and cellulosic.

All these observations are of the greatest interest for facilitating the survey of root consignments, for estimating their value and for knowing whether roots of *Derris* or those of cubé and timbó are under observation.

(e) PREPARATION OF MILLED ROOTS.

For the preparation of the milled roots of cubé the following operations at least are required: (a) cutting into sections or chopping of the roots; (b) crushing; (c) pulverisation; (d) grading of the powders by degree of fineness; (e) rendering the product homogeneous; (f) analysis; (g) blending and standardization in as to obtain a definite percentage figure of rotenone and of total extract.

For chopping the roots of cubé, machines of the "Rotary Cutter" type are used. In small scale industry, a guillotine chopper or even an ordinary knife may be utilized.

The roots are crushed in mortars with hammers which make 1600 to 1800 revolutions a minute; the coarse powder obtained is directed by means of bellows on to sieves which retain the coarser elements. In the course of this operation all that is necessary is to take care that material is fed to the mortar in such a way as to avoid overheating and the rise of the temperature above 75° C.

The cubé powder to be utilized as powder or in suspension in soapy water must pass through mesh 200.

In American factories crushing is done in lots of 500 kg. Each milled lot is then placed in a mixer so as to obtain as homogeneous a powder as possible. Afterwards, a representative sample is taken and analysed by suitable methods to be described later. The cubé powders contain from 4 to 5 per cent. of rotenone.

This content is usually reduced in commercial insecticides, by means of mixture with neutral substances, to a percentage of 0.75 to 1. The powder also may be placed in suspension in a soap emulsion. Liquid insecticides thus prepared usually contain 3 kg. of cubé root powder, with 5 per cent. of rotenone and 15 per cent. of total extract, to 500 litres of water. This quantity is enough for the treatment of one hectare.

#### DIFFERENCES BETWEEN THE POWDERS OF DERRIS AND OF LONCHOCARPUS.

It is advisable to note the differences between the powders of *Lonchocarpus* and those of *Derris*, so as to be in a position to detect mixtures and adulterations.

In the first place, the roots of the two kinds of plant behave differently during milling. *Derris* roots are hard and tough, their reaction to crushing is thus quite satisfactory and little debris is left. On the other hand, *Lonchocarpus* roots are friable and resemble wood that is beginning to rot; they thus leave more wood debris in the process of crushing.

*Derris* powders have a pleasant characteristic odour; the colour is brownish but may sometimes be lighter tending towards beige. In any case the tint is always a warm one, never with any tinge of green or grey.

*Lonchocarpus* powders diffuse an unpleasant odour; they smell of mould. Their colour is greenish yellow or grey, never tending towards brown, even for the darkest powders.

Unfortunately these very marked differences of odour and coloration cannot be employed for the analysis of mixtures of the two powders, especially when a third substance has been used as filler. Microscopic analysis then becomes necessary. Under microscopic examination, the powders of the two kinds differ very little. The following elements are found: ligneous vascular tissue, cells containing crystals, pitted vessels and cells, concreted cells, fragments of parenchyma, gum and tannic acid. The starch grains are the only elements by which it is possible to distinguish the plant from which the powder analysed is derived. The starch grains of *Derris* usually have the hilum pointed; the hilum of starch grains of *Lonchocarpus* is most often in the form of a crack. A large proportion of starch grains of *Derris* are found without hilum. A. DIAKONOFF has made a careful study of the relative dimensions of starch grains of *Derris* and of *Lonchocarpus*; he has reproduced on a graph the results reached; he found that the length of the starch grains of *Derris* is on an average 6.38 with a deviation of 0.14  $\mu$ . and that that of the starch grains of *Lonchocarpus* was 9.80  $\mu$ . with a deviation of 0.2  $\mu$ . From these studies and measurements it is clear that microscopic analysis of the starch grains enables detection in a mixture of the presence of powders of *Lonchocarpus* and of *Derris*.

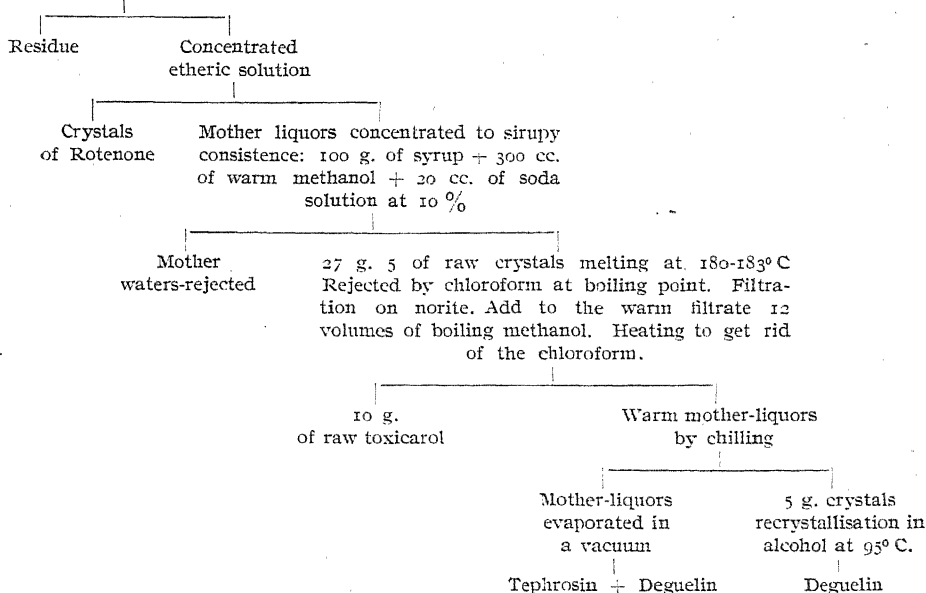

#### CHEMICAL COMPOSITION OF LONCHOCARPUS ROOTS.

The first chemical study of *Lonchocarpus* roots was made by GEOFFROY who in 1895 succeeded in extracting from *Robinia nicou* (now *Lonchocarpus nicou*) a substance he called nicoulin. The properties of nicoulin, as described by GEOFF-

FROY, show that it was the substance now extracted from the roots of *Lonchocarpus nicou* and known under the name of rotenone.

In 1931, CLARK carried the analysis of *Lonchocarpus* roots to a further point. Treating the mother liquors of crystallisation of rotenone by means of potassium, he isolated raw crystals fusing at 180-185° C, very similar to the tephrosin previously obtained. These crystals are simply a mixture of the three following compounds: deguelin, tephrosin and toxicarol. The technique followed by CLARK for proceeding to this extraction is synthesized in the following formula:

Roots of *Lonchocarpus nicou*  
Extraction by ether

CLARK has thus obtained from roots of *Lonchocarpus nicou* on an average 5 per cent. of rotenone, 1.6 per cent. of raw deguelin, 1.9 per cent. of a mixture of deguelin and tephrosin (by evaporation of the mother-liquors of crystallisation of the deguelin) and 1.8 per cent. of toxicarol. In addition to these well defined substances, resins of unknown composition remain.

Of the substances isolated in the nearly pure state from the roots, rotenone is the most important, since it is both the most abundant and also the most toxic. Investigations have in fact shown that the toxicity of the residue, after extraction of the rotenone, is equal to 40 per cent. of that of the rotenone.

The rotenone content of 23 samples of cubé roots analysed by JONES varied from 0.8 to 11.2 per cent., the average content being 5.4 per cent. This average is fairly high, compared with the other fish-poisoning plants of commerce. The same chemist has analysed *Derris* roots the rotenone content of which varied from 0 to 7 per cent. with an average of 2.5 per cent. only.

It is of interest to examine the causes of the variations of rotenone content in the roots. Observations made by ROARK enabled him to report that the slender roots contain more rotenone than roots with an average diameter. It has been possible to verify this observation at the Chemical Laboratory of the Agricultural Experiment Station of La Molina, Peru.

The following figures have been obtained:

TABLE II. — *Rotenone content of cubé roots, according to diameters.*

(after the analyses made at La Mollina).

	Diameter of roots 1 to 2 cm.	Diameter of roots 0.7 to 1 cm	Diameter of roots equal to or less than 0.7 cm.
% rotenone . . . . .	4.5	5.2	6.0
% total extract . . . . .	15.2	17.8	20.4

It is thus established that the rotenone content of the roots is in inverse ratio to their diameter.

The extracts obtained by the various solvents (chloroform, carbon tetrachloride, ether, etc.) on the same sample do not give the same figure, and moreover the differences are not constant and are consequently difficult to interpret. When operating on cubé roots, the toxicity of the extracts obtained with the various solvents is nearly equivalent; when operating on *Derris* roots, the extracts on the contrary do not show the same toxicity. According to A. D. LICHTBODY the extract made by acetone is the most toxic, those made by chloroform and by ether come next, then last the carbon tetrachloride extract.

There is an essential difference in chemical composition between the roots of cubé and those of *Derris*. In cubé roots the ratio between the rotenone content and the total extract is nearly constant, and is approximately 1 to 3 when the extraction is made by means of carbon tetrachloride. On the contrary, in the case of *Derris*, the content in extract shows no ratio to the rotenone content.

Summarising, the various analyses of roots of *Lonchocarpus* and of *Derris* show that:

(1) The roots of *Lonchocarpus* contain on an average more rotenone than those of *Derris* and it is the most slender of these roots which have the highest rotenone content.

(2) Roots of *Lonchocarpus*, as well as of *Derris*, contain other toxic substances, and in particular, toxicarol, tephrosin and deguelin.

(3) The toxicity of the total extract of *Lonchocarpus* roots does not depend on the solvent utilized, while that of the total extract of *Derris* roots does so depend.

(4) The ratio between the rotenone content and the total extract is nearly constant with *Lonchocarpus* roots, while this is not the case with *Derris* roots.

#### PREPARATION OF EXTRACTS OF LONCHOCARPUS ROOTS.

The procedure followed for obtaining total extracts of cubé roots closely resembles that employed with other plant products. The two methods most in use are the method of extraction by diffusion, operating in cold, and the Soxhlet method, operating in heat. The former method has the indisputable advantage of avoiding the too violent heating of the active principles, but has the disadvantage that the extraction of the powder is less complete than with the second method. With the Soxhlet method, it has been found possible to regulate the temperature so that the active principles are not affected. It is more usual to adopt this latter method.

There are in addition a certain number of other processes of industrial extraction which have recently been patented.

The principal solvents which may be used for industrial extraction of the active substances of the roots of cubé are: acetone, benzene, carbon tetrachloride and ethylene bichloride. Carbon tetrachloride is used relatively little as it dissolves very little rotenone, and produces corrosive substances which injure the apparatus. Benzene is scarcely ever employed as it is excessively toxic for the operators. Acetone is much used, as it is easy to recover. But the solvent most in use, in Peru in particular, is ethylene bichloride. Extracts of cubé prepared with this last solvent dissolve more easily in kerosene than extracts prepared with acetone, a feature of great importance for the manufacture of insecticides.

#### PREPARATION OF INSECTICIDES AND OF ANTIPARASITIC PRODUCTS ON A CUBÉ BASIS.

At the La Molina Experiment Station, in Peru, numerous experiments have been carried out in the preparation of insecticides and anti-parasitic products with a cubé basis. A summary of the results obtained in the course of these trials may be given.

The principal insecticide and antiparasitic preparations with a cubé basis are as follows:

- (1) Standardized cubé root powder, for farm use or for destruction of the parasites of domestic animals;
- (2) Liquid extract of cubé standardized for the same uses.
- (3) Extract of cubé in the form of a paste used for producing liquid extracts by dilution in a suitable solvent.
- (4) Liquid insecticide for household use with a cubé extract basis.
- (5) Insecticide powder for household use with a basis of cubé roots, pyrethrum flowers and naphthaline, known as « Pi-cu-naf ».
- (6) Liquid insecticide for household use with a basis of extract of cubé root, extract of flowers of pyrethrum, perfume and kerosene, to which the name of « Picu-molina » has been given.

(to be concluded).

J. LEGROS

## AGRICULTURAL SERVICES SUPPLIED BY RAILWAY COMPANIES

### Introduction.

To those engaged in the study of agricultural questions new problems seem to present themselves every day. The fundamental conceptions on which farming was based in the old days have been swept away. Agriculture has been affected by the political and economic changes that have taken place since the rise of industry. Demand has changed in volume and distribution, necessitating an adaptation of production. The food problem itself has changed in regard to both men and animals. Hygiene has become a necessity. The farmer of the present day must acquire a considerable amount of abstract knowledge if he is to maintain his place in the economic life of his country and move with the times. The empiric methods of farming which were transmitted to him from past generations are no longer adequate in a world where men *plan* economic and technical evolution by working along lines in which the exigencies of natural economic laws play an ever smaller part.

The education of the small farmer is difficult but necessary: since, however, the education of children has not always been sufficient and has lagged behind the march of progress, it is advisable to educate the adults. It is for this reason that so much importance is attached to agricultural instruction.

The isolation of farmers, even in densely populated countries, has always been a serious obstacle to instruction and propaganda. It is difficult to reach people whose occupation compels them to live in country districts where means of communication are often scanty. Propaganda, if it is to be effective, must appeal to the mentality of the farmer and be brought almost to his door.

The agricultural services formed by the railway companies realized how valuable an instrument of penetration and propaganda they possessed in the railway. Their efforts were mainly directed towards the instruction of farmers and, by means of the railway, they could transport cumbersome and expensive demonstration materials which represented the latest achievements of modern science. Their efforts have been successful.

It was felt that it would be of interest to make an enquiry into the activities of the various railway agricultural services in different countries. In reply to this enquiry a number of answers were received and we are grateful to those organizations who supplied us with the information requested. It is clear that instruction and propaganda by means of exhibition-trains (the special activity of the agricultural service) has met with the greatest success in those countries where centralization and administrative organization are not far advanced and where there are large tracts of agricultural land and few urban centres.

We will mention first those countries in which, according to their own statements, agricultural services do not exist and where the railway companies have done little or no work in this field.

The *Bulgarian* port railways have provided no agricultural service nor have they organized exhibition-trains, but the subject is under consideration. The same is true of *Great Britain*, *Denmark* and *Greece*, the railways confining their assistance to the reduction of rates for agricultural produce.

The managers of the *Hungarian* railways have for some years considered the organization of exhibition-trains for the dissemination of agricultural and commercial information; up to the present no definite plan has been drawn up nor have such trains been run.

No railway agricultural service exists in *Italy* but there is a « works service » which studies all questions connected with agriculture and forestry. For demonstration and propaganda purposes on behalf of superior timber suitable for sleepers this service has devoted some attention to the cultivation of eucalyptuses of the *rostrata* and resinous varieties on land belonging to the Administration. In the interest of autarchy it also advocates the planting of genista and castor-oil plants along railway embankments.

The railway companies of *Latvia* and the *Netherlands* have not undertaken agricultural propaganda of any kind.

The Polish Railway have not organized exhibition trains but have done some propaganda by setting up model holdings for horticulture, apiculture and poultry-breeding. As in *Yugoslavia*, these holdings are allotted only to railway employees. The *Romanian* and *Swiss* railway companies carry on no agricultural propaganda. In *Switzerland*, however, an exhibition-train circulated on the Federal railways during the years 1934-36 but it was mainly organized by the Zurich co-operative association for travelling exhibitions. The central propaganda office for products of Swiss fruit growing and viticulture collaborated by supplying samples of wine, cider, honey, etc.

The Ministry of Railways of *Czechoslovakia* grants considerable tariff concessions for the transport of agricultural products. Farmers' organizations are represented on the railway rates committee, which acts as a advisory body to the Ministry on all questions of principle regarding rates.

In *Turkey* no propaganda is carried on, unless a nursery which has existed since 1928 for the purpose of supplying railway stations with trees may be included under this heading.

Neither agricultural services nor exhibition-trains have been organized in *Australia*.

In *South America* the Chilean railways co-operate in the agricultural propaganda of the Ministry of Agriculture by granting reductions in freight rates. No special agricultural programme has been drawn up by the Colombian railway authorities.

Those countries which, in reply to our enquiry, stated that they provide agricultural services are the following: France and Yugoslavia in *Europe*; Canada and the United States in *America*; the Union of South Africa, Australia (Victoria) and New Zealand.

## Canada.

### HISTORICAL.

As Canada was a colony, the attention of the railway companies was soon turned towards agriculture. The first railway line in Canada was constructed in 1836 and large-scale work begun in 1851 but it was not until some years

later, when the Canadian Pacific line was opened, connecting Montreal with Vancouver, a distance of 4,675 km., that the railway companies entered upon a period of definite agricultural activity. In 1927 the Canadian Pacific Railway had a total length of 32,421 km. and the Company has done much for the benefit of agriculture. Unfortunately no information on this subject is available.

We know, however, that the Canadian National Railways Company has a vast agricultural programme, a summary of which is given below. After the World War the Canadian Northern and the Trunk Pacific Railways, which were in difficulties, were absorbed in the Canadian National Railways.

The Canadian railway lines have a total length of 90,000 km.

#### THE CANADIAN NATIONAL RAILWAYS.

ESTABLISHMENT OF AN AGRICULTURAL SERVICE. — On January 1, 1925, the Canadian National Railways organized an agricultural service known as the Colonization and Agriculture Department.

ACTIVITIES OF THE SERVICE: ITS OBJECTS AND RESULTS. — The work of the Agriculture Department is to develop an association with those agencies which play a part in increasing and developing new sources of production. This is accomplished by working closely with representatives of the Federal and Provincial Governments, commercial agricultural agencies, farmers' organizations, Agricultural Colleges, Chambers of Commerce, Service Clubs and the daily and weekly press. The Department also publishes pamphlets, circulars, etc. and forms a connecting link between the agricultural industry and the railway company. All its assistance is for the development of a more profitable agriculture which at the same time usually results in an increase in railway traffic.

Some examples of the work of the Agricultural Service are given below:—

(a) The Soil Improvement Campaign, through the operation of a special Soils Train, started ten years ago, was an important factor in increasing almost ten times the use of agricultural limestone and trebling the sale of fertilizers in the Province of Quebec.

(b) In the western provinces the Service has organized Community Progress Competitions in foreign-speaking communities. No such effort had been attempted previously to develop Canadian citizenship and a number of very interesting community agricultural projects have been developed as a result of these competitions. Thus, from the cash prize secured, one community purchased several purebred stallions and during 1937, from this district alone, 20 carloads of horses were sold.

(c) The development of new breeding and feeding centres for horses, cattle, sheep and pigs and the introduction of improved sires—for example, by the western horse breeding clubs—together with better varieties of grain have helped to render agriculture more profitable.

(d) The growing of green peas on the Gaspé Coast, started some years ago by the Agriculture Department, now represents an additional yearly income of about \$ 30,000 for the farmers of that district.

(e) Though there are many peat bogs in Canada, it was not until the Department found new uses for this material in agricultural and industrial enterprises that any progress was made in supplying the Canadian market which had largely been supplied by importations from other countries. The quality of peat has been improved and the demand for good Canadian peat is increasing. In the year 1937 sixty carloads were sold from the one bog the Department had helped to develop. This was new business and in a few years an annual sale of 200 to 300 carloads is anticipated.

(f) The Agricultural Improvement Campaign in the Lake St. John district of Quebec was started as a result of a survey of agricultural conditions. Figures indicated a low milk production, with possibilities of raising more hogs subject to the growing of more appropriate crops. This "More Milk per Cow and More Hogs per Farm" project has resulted in the elimination of many cows yielding little milk, in the increased butter fat production of 22 lb. per cow, with the additional sale of over 100 carloads of hogs during the last four years.

(g) New wealth was brought to certain farming districts in the four Eastern Provinces by improved production and marketing methods with small fruits and the salvaging of surplus berries by freezing and canning.

(h) The establishing of seed producing centres at different points in Western Canada, the introduction of better varieties and improved breeding stock through Boys' and Girls Clubs, its participation in organizing agricultural tours, conventions, fairs, sales, field days, short courses of instruction, surveys, lectures and many other varied activities enable the Department to promote the goodwill of the farming people and to increase production on the railway lines.

COOPERATION WITH GOVERNMENT SERVICES. — Agricultural trains have been operated in co-operation with the agricultural departments of the Provinces, and other interested organizations and it is only for reasons of economy that they have recently been discontinued.

CONTROL. — In some cases the agricultural trains are entirely controlled by the Provincial Department of Agriculture; in other cases, they are operated jointly with other Provincial Departments, the Dominion Government, Agricultural Colleges and the railway authorities.

RUNNING OF EXHIBITION TRAINS. — Exhibition trains were operated prior to the formation of the Colonization and Agriculture Department, that is to say, before 1925, as we have seen.

Summer and autumn are usually the most favourable periods for the running of these trains. The policy of the Department is not to have more than one train a year operating in a district on some particular phase of agriculture.

TYPE OF TRAIN USED. — The type of train used for exhibition purposes varies a great deal but usually consists of second-class passenger coaches, varying in number from one to five, from which the seats have been removed. Any livestock carried for demonstration purposes would, of course, be handled in livestock cars or specially built box cars or flat cars.

**STAFF.** — The staff of engineers, lecturers and demonstrators, is recruited from Agricultural Colleges, Government Departments, commercial companies and the railways. All members of the staff are able to give lectures, conduct demonstrations and — in many cases — to show educational films.

**INTERNAL ARRANGEMENT OF EXHIBITION-CARS.** — The arrangement of the demonstration cars depends on the aim pursued. In general, there are several kinds of display exemplifying one or two ideas. In the Soil Train, for instance, there was a laboratory car where soils were given a quick lime test, then a lime car giving experimental results in the form of charts and a small sample of soil with crop displayed where people could actually see for themselves some of the results obtained. The use of lime was also featured in ten factors leading to improved soil fertility. These two cars formed the main feature of the train.

Any other aspect of the question was represented by a third car in which the results of fertilizers were displayed with charts and a summary of experiments. The fourth car was for the purpose of holding meetings when the weather was unfavourable for holding gatherings outside. The fifth was a combination sleeping and dining car for ten members of the staff. In other cases, this last car might be a caboose, which would be used only for clerical work during the day.

**PUBLICITY ORGANIZATION.** — The success of demonstration trains depends largely on the advance publicity in the localities where the train will stop. The most successful trains were organized a year in advance. In the opinion of the Agricultural Department, no one form of publicity is sufficient and the more varied the approach to the subject, the more satisfactory the results will be. This includes press articles, circulars, pamphlets, radio announcements, notices read from the pulpit, municipal councils and schools, distribution of announcements by rural mail and through local organizations and agricultural officials. Where possible, it seems advisable to have interested parties do something themselves, such as bringing a sample of soil for analysis.

**RESULTS OBTAINED.** — The best results were obtained from two Soil Trains operated in 1930 and 1931. These two trains made 72 stops, were visited by 19,500 farmers, and 10,555 soil samples were tested. The Province of Quebec, where these trains were operated used in 1928 some 4,628 tons of agricultural limestone and in 1937, some 42,065 tons were distributed and the use of fertilizers has about trebled in the same interval.

The railways have not given any encouragement to propaganda by motor truck. Some Provincial Governments attempted it but, as it was not so satisfactory, it has been discontinued.

## France.

**INTRODUCTION OF AGRICULTURAL SERVICES.** — The transport of agricultural produce represents a considerable amount of traffic on French railways and the old railway companies gave special attention to every means of promoting

this part of national activity. Hence the formation of "agricultural services" or "agricultural propaganda services" by the various Companies. These were introduced as follows:

- Compagnie Paris-Orléans in 1903
- » Paris Lyon Méditerranée en 1912
- » Etat in 1914
- » Midi in 1920
- » Alsace Lorraine in 1924.

The Nord and Est companies instructed some of their commercial inspectors to study agricultural questions.

This organization was maintained in its general structure when the French railways were nationalized (January 1, 1938) and merged into the *Société Nationale des Chemins de Fer Français*.

OBJECTS. — The agricultural activities of the railways comprise two series of measures, one technical and the other commercial.

The technical measures aim at the introduction, development or improvement of crops or livestock calculated to increase the tonnage of railway traffic, such measures to be carried out in regions recognized as suitable for the purpose. In so directing production due account is taken of consumers' needs and preferences.

The commercial measures are designed to turn the attention of producers and dealers to existing but partially neglected markets, to customers' demands in respect of quality and quantity, to foreign competition, and to new methods and implements which might be adopted with advantage.

METHODS. — A number of methods are adopted varying according to circumstances. They include:

Lectures illustrated by films.

Practical demonstrations (pruning of fruit trees, treatment of plant diseases, etc.).

Distribution at reduced prices (in some cases, free of charge) of plants seeds, etc.

Organization of congresses.

Study tours in France and other countries.

Organization of exhibitions and propaganda trains.

Subsidies to research stations for the study of certain questions.

The awarding of medals and diplomas for success in certain competitions.

ORGANIZATION OF EXHIBITION TRAINS. — Some years ago the *Compagnie des Chemins de Fer du Nord* placed at the disposal of the Regional Agricultural Services a demonstration train composed of three cars: one cinema car for the projection of documentary and technical films and for lectures; and two cars arranged as show-rooms for products and apparatus. This train, which has travelled on various occasions in different departments in the north of France, was intended for the instruction of farmers in all that concerns fruit production, arboriculture and the antiparasite and anticryptogamic treatment of fruit-trees.

The services interested are allowed perfect freedom as to the manner in which they utilize the material entrusted to them. The agricultural instructors usually obtain the material necessary for their demonstrations from the manufacturers.

*La Compagnie des Chemins de Fer d'Alsace et de Lorraine* has a very active agricultural service composed of a director and an assistant agricultural engineer; so far, however, it has not organized exhibition trains. Propaganda trains, including one illustrating the uses of electricity on farms, have circulated on the Alsace Lorraine railways, but they were equipped and run by other railway companies. The electricity train was run, and the public admitted, free of charge.

*La Compagnie des Chemins de Fer de l'Etat*, in collaboration with the National Fertilizer Propaganda Association, organized a train for fertilizers and selected seeds. During the period 1929-36 this train made 13 circuits, mainly during the months of January, February, September and October. It also travelled on the lines of the *Compagnie du Midi* from November 20 to December 11, 1933. The *Chemins de Fer de l'Etat* also ran two propaganda trains to encourage the consumption of sea-fish and the use of wood fuel.

The *Compagnie Paris-Orléans*, with the assistance of various organizations for electricity propaganda, equipped an exhibition train with rural electric appliances, which circulated on the lines of the Company from November 16, 1930 to January 11, 1931, and also on those of the *Midi* and the *Alsace and Lorraine Companies*, as mentioned above.

Speaking generally, the staff attached to each train comprised engineers and officials belonging to the railway and representatives of various propaganda organizations. The last named gave lectures, demonstrations and, in some cases, showed educational films.

(1) PROPAGANDA TRAIN FOR FERTILIZERS AND SELECTED SEEDS. — The contents of this train were as follows:

- (a) samples of all kinds of fertilizers and literature on their use;
- (b) a collection of superior varieties of cereals specially adapted to the geological and climatic conditions of western France. All groups interested in the production of, or trade in fertilizers, together with the seed-exhibitions Committee, participated in this enterprise, which was under the patronage of the Minister of Agriculture.

The train was composed of six cars specially arranged for an exhibition, with electric light, handsome carpets, photographs, graphs, and simple but striking formulae. The outside of the train was painted a cream colour. In addition there was a workshop car (for the generation of electricity) and a truck containing reserve material.

Four of the six cars contained everything relating to:—

- (1) Lime dressing and sylvinitic;
- (2) Basic slag, cyanamide and nitrate of soda;
- (3) Superphosphates and sulphate of ammonia;
- (4) Various fertilizers (nitrate of lime, nitrate of ammonia, urea, etc.).

A fifth car was reserved for selected seeds.

Finally, a sixth car showing isotherms completed the train for the purpose of showing farmers the advantage of refrigeration in the transport of perishable products. Propaganda agents appointed by the Fertilizer Propaganda Association were always present, ready to reply to technical or practical questions, thousands of which were put to them.

At each stopping place the Director of the agricultural services of the department the train was traversing gave a practical lecture on the use of fertilizers.

In order to encourage the visitors to make use of fertilizers, a free lottery was organized at each stage of the itinerary, the expense being borne by those responsible for the exhibition. Holders of the winning numbers received a certain amount of fertilizer accompanied by directions for its use. 130 tons of fertilizers were thus distributed.

Throughout the itinerary the train was always preceded by wide publicity.

(2) PROPAGANDA TRAIN FOR THE CONSUMPTION OF SEA-FISH. — The object of this propaganda train was to convince farmers of the food value and digestive quality of fish, hitherto but little recognized since fish is generally regarded as an additional expense rather than an article of food which, like meat, can be the basis of a meal.

This venture, which took place during May and June 1930, under the auspices of the Minister of the Mercantile Marine was one of the most original and most popular examples of this form of propaganda.

The train consisted of five cars communicating with each other, and a truck painted green and blue; a white, fleecy effect represented waves.

The two first cars were devoted to a realistic representation, provided by the Museum of La Rochelle of all edible sea-fish, together with a collection of appropriate literature on fishing and the many uses to which fish can be put.

The third car was reserved for the subject of fishing, including the processing and culinary uses of cod and herring. All that the *Association Française du Froid* has popularized since its inception concerning the use of refrigeration in the sea-fish industry was presented in a refrigeration car.

In another car visitors could watch the preparation by cookery-demonstrators of fish afterwards consumed by the spectators under a tent outside the car.

The principal accessories of this kitchen-car were an oven, an automatic plate-washer and a device for eliminating cooking odours.

(3) EXHIBITION TRAIN ON THE USE OF FOREST PRODUCTS AS FUEL. — In order to mitigate the crisis in the fuel trade the Chemins de Fer de l'Etat ran an exhibition-train from June 3 to July 15, 1937, to promote the use of wood fuels and forest products.

This enterprise, which was under the patronage of the Under-Secretary of the Ministry of Agriculture was of national interest and was organized with the collaboration of the Chemins de Fer de l'Est, of the majority of the wood and charcoal corporations and of a large number of manufacturers of carbonization ovens, gazogenes, light gas motors and electrogen groups, charcoal crushers, boilers heated by wood or charcoal, stoves and other domestic appliances involving the use of wood fuel.

The exhibition train, consisting of seven specially adapted cars, stopped in some thirty localities.

Lectures were given at some of these by an official of the Waters and Forests department.

(4) EXHIBITION TRAIN FOR THE USE OF ELECTRICITY IN THE COUNTRY. — In order to make known to those living in the country the advantages of electricity the *Compagnie d'Orléans* organized an exhibition-train for this purpose. So successful was the effort that the *Compagnie du Midi* copied it in the area served by their lines.

The exhibition train consisted of ten large cars specially equipped for the concrete demonstration of progress in the practical application of electricity.

*1st car:*

Fixed electric motors.  
Portable electric motors, and motors on barrows.  
Electric apparatus for animals.  
Electric ploughing and threshing.  
Electric pumping.

*2nd car:*

Use of electric power inside farms.

*3rd car:*

Application of electricity to dairy work.  
Application of electricity to baking.  
Application of electricity to laundry work.

*4th car:*

Electric accessories for domestic purposes: the distribution of water, the bathroom, kitchen, pantry, cleaning.

*5th car:*

Scientific lighting.  
Refrigeration plant.  
Heating.

*6th and 7th cars:*

Commercial stands.  
Modern electrical appliances for many and varied purposes.

*8th car:*

Radio stand:  
Electricity as applied to radio installations and gramophones (apparatus, accessories, spare parts, etc.).

*9th car:*

Rural crafts stand.

During the period March 1-April 19 the train covered the entire Orleans line, passing through 14 departments. Demonstrations were given in 38 farming districts.

In many places on the route provision was made for talks, practical demonstrations, lectures and film projections. The propaganda was supplemented by the free distribution to visitors of leaflets and pamphlets.

RESULTS. — The results obtained by the agricultural services of the separate railways cannot be expressed numerically but there can be no doubt that the notable increase in certain kinds of traffic is traceable in part to this source. Thus the tonnage of certain fruits and vegetables transported by passenger train by the P. L. M. rose from 190,000 metric tons in 1910 to 590,000 in 1931 while, as regards the P. O. and *Midi* the tonnage of the same produce rose from 52,000 metric tons in 1907 to 90,000 in 1931.

On the other hand, the success obtained by the various trains described above indicates the importance of the practical results of the propaganda.

The propaganda train for the use of fertilizers and selected seeds visited 288 localities, was run for five years and had most satisfactory results among the 200,000 farmers who visited this travelling exhibition.

The train for the consumption of sea-fish stopped at 22 western centres and was visited during its two months' itinerary by over 130,000 persons, while 2,500 kg. of cooked fish were distributed from its kitchen.

Precise figures showing the results obtained by the other exhibition trains are not available but it is probable that in each case the object was amply attained. It may be expected that this very effective method of propaganda will be further developed.

CONCLUSION. — The idea of agricultural propaganda is due — as is often the case in France — to private initiative. The State adopted the idea, improved upon it and, when the various railway systems were merged, endowed it with power and homogeneity which were hitherto lacking. It is to be hoped that the co-ordination between public and technical education on one hand and the French National Railway Company on the other will become closer. The object lesson given by an exhibition train should be made fruitful by instruction.

*(To be continued).*

## **MISCELLANEOUS INFORMATION**

AGRICULTURAL RESEARCH AND THE WORK OF THE AGRICULTURAL RESEARCH COUNCIL, LONDON. (Lecture delivered by Sir WILLIAM DAMPIER, ex-Secretary of the above Council, before the Farmers Club, 1938).

The Council, established by Royal Charter in 1931, has already issued two Reports covering the total period 1931-35 and a third report is now in the press. From the two former reports it is evident that this body is increasingly able to discharge the duties assigned to it, *viz.*, of directing the expansion of agricultural research to the most important needs of the industry, utilising to the greatest advantage the present and future facilities available at research Institutes and elsewhere, and furthering the coordination of agricultural research work in general. The annual budget of the Council is increasing yearly, and in 1937-38 the Council had at its disposal £ 88,640 for the direct promotion of research.

The Council began its task by a survey of the multifarious work in progress in the country. Six standing Committees were set up to cover the main branches of Agricultural Science: Soils and Plant Nutrition; Plant Physiology, Breeding and Disease; Animal Nutrition and Breeding; Animal Diseases; Dairying and Animal Products; Agricultural Economics. It appointed *ad hoc* committees, often including as members eminent experts from outside the Council, to deal with special subjects such as agricultural engineering, application of electricity to crops, consideration of programmes, finance, etc.

Much new knowledge is being acquired in the different divisions of agricultural science. Special soil studies are being made at Rothamsted, Oxford and near Aberdeen. Adopting the recent methods of LUNDAGÄRDH, spectroscopic analyses of soil extracts injected into an acetylene flame can be usefully made at a cost of about one penny each. The study of the crumb structure of soil has led to a new view: soil seems to be a series of cells connected by narrow necks. After rain these cells are full of water, and it is only the surplus water that leaches away. The problem of fruit-growing is dealt with at Long Aston and East Malling. At the former station it has been found, for example, that apples show no sharp segregation of characters; in polyploids several chromosomes are concerned in one character. At the latter station, the conversion of one apple variety into another and bringing it into full bearing within two years have been made feasible by inserting a number of grafts. WOODMAN'S finding that grass cut when 4-6 inches high and dried in hot air or furnace gases, contained almost as much nutriment as fresh grass, has brought into being four types of drying machines. The number of grass driers at work in Great Britain in 1937 was 75. The inquiry into contagious abortion in cattle has led to the establishment by the Council of a special Field Station at Compton in Berkshire. The aim of this Station is to breed disease-free animals for use in the different research stations. The Animal Diseases Research Association at Moredun near Edinburgh has discovered an effective vaccine against braxy, a disease which attacks sheep. A number of problems in Dairy Science are being treated at the respective Institutes in Shinfield, Kirkhill, Edinburgh, and London. Hitherto it had been assumed that the "plate-count" was the final standard of reference in estimating the number of living bacteria in milk. WILSON found that the chemical reduction, traced by the decolorisation of methylene blue, was a simple and rapid test for the cleanliness and keeping qua-

lities of milk. This test, in conjunction with the coliform test, was officially accepted in England in 1936.

All research work involving a number of observations need statistical guidance, both for the lay-out of plans and interpretation of results. Bigger centres have their own statisticians, and it is suggested that smaller Institutes within reasonable distance from each other might combine to secure the services of a statistician.

Fundamental economic problems and questions concerning the agricultural aspect of general economic policy are being treated at Oxford and at various other centres with advisory economists. The work of the Cambridge economists in surveying a large number of East Anglian farms proved so useful in formulating the agricultural policy that in 1936 it was determined to extend the method to other centres, so that a complete survey of the country might be obtained. Some time ago, an Economic Section under Mr. R. R. ENFIELD was established at the Ministry of Agriculture and Fisheries to study agricultural economics from the political aspect.

NEW SUGAR BEET LIFTERS. — While the sugar beet lifters in use in Europe are all more or less built on the principle of lifting the beet after topping, a new machine recently invented in the United States lifts the beets and undetached leaves in a single operation; it is therefore a sort of "Combine" for beet-lifting, and renders the work entirely mechanical. Mounted on rubber tyres and weighing 12.5 quintals, this machine requires a tractive power of 20-25 HP on the draw bar. The machine is operated by the tractor's power take-off.

The machine deals with one row at a time; under normal conditions  $\frac{1}{4}$  of a hectare (approximately  $\frac{1}{2}$  an acre), should be cleared in an hour. The following is a description of the way in which the machine operates: first of all two teeth something like those for gathering sheaves, raise the leaves falling naturally to the right and left of the beet and draw them into a bunch. Immediately behind these leaf lifters, two endless rubber chains, which are inclined forward and operated by an inverse movement to that of the tractor, take the beets by the top and grip them; simultaneously, a pair of lifting blades comes into action from beneath. While the blades are loosening the beet, the two endless chains, raised towards the back, draw the beet from the soil. The lifting is executed almost vertically, because the rate at which the chains move towards the back is much about the same as that at which the tractor progresses. In this way the beets are cleaner when lifted than is the case with the methods usually employed.

The beet is carried along by the chain and after passing through two toothed rollers, reaches a topping device and then a cleaner; finally the beets are either collected in a receptacle which is emptied from time to time, or are carried by an elevator to a cart which accompanies the machine.

The beet leaves are immediately arranged in rows or collected in another receptacle which drops them in little heaps.

The tractor requires only its driver and a man to operate the "Combine". The machine has not yet been put on the market.

INTERNATIONAL SOIL SCIENCE ASSOCIATION. — Volumes 1 and 2 of the Proceedings of the International Soil Science Association were published in 1925 and 1926 by the International Institute of Agriculture, Rome. Their contents consisted mainly of original publications, summaries, a bibliography and reports.

During the 1st Washington Congress (June 1927) and in agreement with the International Institute of Agriculture, it was resolved to publish these proceedings under a new form, so that thereafter they should contain only:

- (1) The reports of the International Soil Science Associations;
- (2) Summaries of publications.

At the same time Prof. SCHUCHT undertook to edit these proceedings in Berlin. The last number of these Proceedings, the well-known green book, was published for the last time in December 1938. For twelve years Prof. SCHUCHT has devoted much energy and time to this very important work and the Presidency wishes to express its sincere gratitude for his disinterested work for the benefit of the Association.

January 1939.

D. J. HISSINK, Assistant President and Hon. Secretary General. —  
A. DEMOLON, Vice President. — A. A. JARLOV, Vice President. —  
A. BRIZI, Secretary General of the International Institute of Agriculture, Representative of the International Institute of Agriculture. —  
G. DE ANGELIS D'OSSAT, J. G. LIPMAN, E. JOHN RUSSELL, ex officio Members.

YIELD AND QUALITY OF OLIVE OIL IN RELATION TO SEASONAL CONDITIONS. — For eight years Prof. V. BRANDONISIO has been carrying out a series of experiments at the Bari Experiment Station with a view to establishing the relations between the development, ripening and degree of infection of olives on the one hand, and of the yield and quality of the oil on the other, under practical conditions for the utilization of the olives.

Experiments were made with the following varieties: Paesana, Coratina, Leccese, Cima di Mola, Pizuta, Rotondella and Cellina di Cassano, all widely cultivated in the important oil-producing region of Apulia. The experiments have demonstrated: (1) that the date when the yield is greatest is in strict ratio to the course of the season and to *Dacus* attacks, and that meteorological factors and attacks of the fly also cause fluctuations which are often quite considerable from one year to the other in the yield of a given variety of olives; (2) as the fruit ripens the oil content increases up to a certain maximum (optimum period for picking) after which it decreases; (3) *Dacus* attacks greatly diminish the chemical and organoleptic qualities of the oil; in fact, acidity which, when work is carried out under good conditions, can be kept below 1 per cent. in years when no attacks of *Dacus* occur, attains an average of 4.5 per cent. in years when the olives are attacked by *Dacus*; in olives which have been attacked by the fly, the composition of the oil is no longer normal, the solid glycerines and the average of non-saponifiable matter increasing, while the oils have a marked tendency to become rancid; (4) in the years when the olives have been attacked by *Dacus* a much larger quantity of residuals is obtained than from healthy olives; this is explained by the higher weight percentage of the stone as compared with the pulp, partly destroyed by the fly; finally the average quantity of fats has been found to be higher in the

residuals of olives attacked by the fly than it is in those of healthy olives. This is explained by the difficulties so often encountered in crushing olives during the years when the *Dacus* attacks have been severe.

A. P.

## TECHNICAL BIBLIOGRAPHY

TOBEY, J. A., *The legal aspects of Milk Control*. International Association of Milk Sellers. Chicago III, 1936, p. 102.

Modern Science and human experience have abundantly proved that milk, "the most quite perfect food", is indispensable in the diet of all infants and young children and that the health of persons of every age benefits from the natural consumption of milk and its derivatives.

The importance of this food for public health is evident, and is sufficient explanation of the fact that all States have sooner or later instituted legislative control of milk, with varying degrees of strictness. Such control is the more necessary as milk, to a greater extent than any other food, is liable to fraudulent handling, adulterations and contamination. For this reason, impure milk represents a much more important factor in public life than pure milk.

"The Legal Aspects of Milk Control" is the work of a competent writer and is supplemented by a full bibliography. Dr. Tobey treats the whole subject with remarkable clearness in 10 chapters, summarised as follows:—

I. — Reasons for the public control of milk: Introductory, Court-Made Law, The Food Value of Milk, The Dairy Industry, Epidemics of Milk-Borne Diseases, Milk and the Law.

II. — The sanitary Regulation of Milk by the State: The Police Power, Milk Control and the United States Supreme Court, Decisions by Other Courts.

III. — Municipal Control of Milk: Ordinances, Boards of Health, The Content of a Milk Ordinance.

IV. — Licenses and Permits: Classification of Licenses, Cost of Licenses, Territorial Jurisdiction, Administration of Licenses, Revocation of Licenses, Contracts of Unlicensed Dealers.

V. — Standards for Milk and Dairy Products: Chemical Standards, Cream, Chocolate Milk, Butter and Butter Substitutes, Filled Milk and Cheese, Ice Cream, Other Dairy Products, The Intent of the Seller, The Grading of Milk, Samples.

VI. — Inspection, Sanitation and Seizure of Milk: Inspection of Dairies, Inspections Beyond City Limits, Certified Milk, Closing of Dairies, Sanitation of Milk Supplies, Embargoes on Unwholesome Milk, Seizure and Destruction of Milk.

VII. — Tuberculin Testing and the Health of Dairy Cattle: Bovine Tuberculosis, Court Decisions on Tuberculin Testing, The Eradication of Bovine Tuberculosis, Destruction of Diseased Cattle, Bang's Disease, Feeding of Cattle.

VIII. — Pasteurization: Court Decisions on Pasteurization, Pasteurization in the City Where Milk is Sold; Fees for Pasteurization, Other Decisions on Pasteurization, Pasteurization Not Upheld.

IX. — Containers for Milk: Prohibition of the Sale of Loose Milk, Cleanliness of Containers, Data on Bottles and Caps, Identification and Ownership of Bottles.

X. — Liability in Connection with Dairy Products: Liability for Unwholesome Dairy Products, Deliveries to Schools and Hospitals, Glass in Milk, Liability for Disease Due to Milk, Liability of Health Officials, Newspapers and Libel, Interference With Deliveries, Contracts.

The work gives an exact survey of the legal aspect of milk control in the United States of America, of value not only to the United States but also to other countries.

### CITRUS CULTIVATION IN THE U. S. S. R.

Citrus fruit cultivation in the U. S. S. R. is of very recent introduction, although in the seventeenth century there were some small groves near what is now the frontier separating the Soviet Union from Turkey.

Citrus fruit growing, mostly of *Unshiu* mandarines, was started on an industrial scale in 1897, but there was little development; in 1912 there were only 200,000 trees on an area of about 400 hectares. During the world war and the civil war, this area decreased considerably, and by 1920 had been reduced to 160 hectares. In 1921 the Government prepared an extensive programme for the industrial development of citrus cultivation, but the results of the first seven years' operation were not very encouraging, and in 1928 the total area planted to citrus fruit trees was barely 600 hectares. Since then, however, this branch of agriculture has made more rapid progress and by the end of 1937 6,450 hectares of land were under citrus fruit trees, as against 3,400 in 1935, and 2,100 in 1932. According to the last five-year plan, 20,000 hectares should be planted with citrus trees by 1940.

Development has been greatest in Georgia, where the groves are planted along the shores of the Black Sea, between the Turkish frontier and the town of Sochi, penetrating into the interior along the Rion valley, as far as the Samtredi district and in the Guria district as far as Ozurgeti. From Sochi to the Turkish frontier most of the orange trees are planted singly and are rarely found in groves. These are old trees which have never been grafted but which frequently yield heavy crops (from 4 to 5 thousand fruits per tree).

According to the 1933 census, the principal centres of cultivation are Adzhar, where 68 per cent. of the groves are situated, Abkhazia (19 per cent) and other districts (13 per cent).

At the beginning of 1938 the «sovkhoz» (State farms), held 1,893 of the 6,450 hectares of citrus fruit trees while 4,557 hectares belonged to the «kolkhoz» (collective farms) and to peasants.

In 1932, at the beginning of the second five-year plan, a study was made of the various species and varieties of *Citrus* acclimatized in the nurseries created for the purpose, as well as of the agroclimatologic and agrotechnical conditions of the districts best suited to the crop. In order to ensure the execution of the plan aiming at increasing the area under citrus to 20,000 hectares by 1940, extensive nurseries have been created in various parts of Georgia, covering in all about 653 hectares and cultivating five million trees.

The first attempts to introduce citrus fruits on the shores of the Caspian Sea date from 1928. An experiment field has been created for the purpose of studying the acclimatization of various varieties of citrus and especially of the Meyer lemon (a Chinese dwarf lemon), the Clementine, Silver Hill and Satsuma mandarines and the Japanese Natsu Mikan tree. A small nursery with an area of half a hectare supplies Unshiu mandarine trees.

Other experiments have been in progress in Central Asia since 1934, carried out by the experiment sub-station at Kyzylatrek in Turkmen, where a collection of citrus varieties was imported in 1935, most of which were grafted on the *Poncirus trifoliata*. In most cases the trees suffered considerably from the excess of chloride of sodium in the soil.

An attempt is also being made to introduce citrus fruit cultivation in the wet sub-tropical districts of Azerbaijan and Krasnodar; more than 100 hectares of citrus trees have already been planted and it is expected that by 1942 the area will have increased to between 2 and 3,000 hectares.

The Ivanovsk experiment station has been attempting since 1932 to extend citrus cultivation (especially lemons) further north. In 1937 this station had nearly 400 lemon trees of different varieties, 12 mandarines, 9 limequats and 6 orange trees. This station is trying to obtain by selection a variety of lemon which will prove highly resistant to cold.

The varieties of citrus fruits found on the shores of the Black Sea are as follows: *C. sinensis* Osbeck, *C. trifoliata*, *C. Aurantium* L., *C. myrtifolia* Rafin., *C. salicifolia* Rafin., *C. Bergamia* Risso, *C. deliciosa* Ten., *C. grandis* Osbeck, *C. Limetta* Risso, *C. limon*, Burm., *C. Medica* L., *C. microcarpa* Bunge, *C. Natsudaidai* Hayata, *C. Paradisi* Macf., *C. Unshiu* Mare, *C. Bigaradia macrocarpa* Risso, *Fortunella japonica* Swingle, *F. Margarita* Swingle, *F. crassifolia* Swingle.

The Plant Institute of the U. S. S. R. at Sukhum uses the following varieties in its citrus improvement work: Mikado, Dai-Dai, Uvatin mikan, and Clementine. Experiments have also been made with the Washington Navel, the Narris Orange, and the Cadenera. The Shamuti (Jaffa) orange is also found, but its characteristics are quite different from those of the Palestinian type: long thorns, straight leaves, etc. By grafting several Mediterranean varieties (Vaniglio sanguino, sanguino Paterno, Maiorca seedless, etc.), on the *Poncirus trifoliata* several very interesting strains have been obtained with cold resistant and good keeping qualities. The acclimatizing nursery at Sukhum has a collection of citrus fruit trees comprising 500 varieties and types.

The Nikitsky Botanical Garden (now Molotov), has been cultivating and acclimatizing American hybrids since 1927 (Morton citrange, Rusk, Rustic, Thomasville citrangquat, Eustis Limequat. The Odessa Botanical Garden has been experimenting since 1935 with the grafting of lemons in particular.

The plan for developing citrus fruit cultivation during the period between 1936 and 1940 includes the following centres: Abkhazia, Adzhar and Western Georgia in the districts of Makharadze, Lanchhuty, Tchokhataury, Zugdidi, Tshakaja, Poti, Hobi, Chhorotshousi, Tsalandjik, Martvill and Abacha. Accord-

ing to this plan, citrus fruits should cover 17,000 hectares in this area by 1940 (9,300 hectares of mandarine trees, 6,765 of lemon trees, and 935 of orange trees). By 1935 3,640 hectares were already planted with citrus fruits, while a further area of 2,355 hectares was planted in 1936 and 1937. The nurseries cover a very large area, amounting in all to 624 hectares. At the beginning of 1938, half the area planted to citrus fruits had not yet begun to produce.

The production for 1936 was 293 million fruits or about 550,000 quintals. Projected plantations during the period 1938-42 are as follows:—

Year	Mandarine trees hectares	Lemon trees hectares	Orange trees hectares	Total hectares	District where trees are to be planted	Total hectares per district
1938 . . . . .	2,983	801	216	4,000	Adzhar	4,530
1939 . . . . .	3,632	1,043	325	5,000		
1940 . . . . .	1,639	4,549	312	6,500	Abkhazia	5,445
1941 . . . . .	1,150	200	150	1,500		
1942 . . . . .	1,150	200	150	1,500	Western Georgia	8,525
Total . . .	10,554	6,703	1,153	18,500		18,500

Since the area occupied by citrus fruit groves was already 6,450 hectares at the end of 1937, according to the plan, by 1942 the area should reach 24,050 hectares as against 21,850 in 1940, so that when the trees reach the productive stage, the U. S. S. R. should have a crop of about 3 million quintals of fruit per annum, or about 1.7 kilograms per inhabitant.

Lemon cultivation in open fields cannot be intensified as the tree is so susceptible to cold. Several authors nevertheless consider that there is a great future, for lemons in particular, in a new type of cultivation, *i. e.*, pot cultivation, also called «indoor cultivation». It appears that shoots and small plants for growing lemon trees in pots in the home are much in demand and a nursery has therefore been created at the Pavlovo experiment sub-station for the cultivation of lemon trees under glass to meet this demand. This type of cultivation is also becoming popular at Baku, Sverdlovsk (Urals) and in the environs of Moscow. Since 1932 the Ivanovsk experiment station has been working on the extension of citrus fruit cultivation to more northerly regions. Although Russian experts maintain that there are excellent prospects for this branch it cannot be considered from anything but the ornamental standpoint, since it is of little practical value for the production of fruit.

The most common varieties of lemon for pot cultivation are the following: (1) *Novo-Afonsky* (New Athos); the tree is of average size, the fruit being also of medium size, long-shaped with a fine skin and tuberous; the pulp is acid but agreeable in flavour, aromatic and seedless; (2) *Eureka*, an American variety producing flowers and fruits almost all the year round, with very acid but aromatic fruit containing few seeds and bearing fruit after the third year; (3) *Lisbonne*, a tall tree with many thorns, long-shaped

or oval fruit with an accentuated point and with a lateral fold, fine skin, very juicy, and with few seeds; this tree usually bears two crops of fruit per year; (4) *Villefranca*, a tall tree, without thorns, long, oval fruit, round at the base, very acid and juicy, and resistant to cold; (5) *Kuzner*, a dwarf tree, productive and without thorns. (6) *Guenuezsky*, a small tree, thornless, very productive, soft-skinned fruit with very acid pulp and few seeds.

The organization of citrus cultivation is centralized in the U. S. S. R. Lemon and Mandarin Cultivation Trust (Limmantrust), founded in 1931 and comprising several sovkhos, kolkhos and peasant farms engaged in citrus cultivation. The trust controls the experimental nurseries and those for the propagation and quarantine of citrus fruit trees. It is anticipated that 4 million plants will have been grafted by 1940. The trust also fixes standards for fruit grading: mandarines are graded as follows: (1) fruit weighing 80 grams; (2) fruit weighing from 70 to 80 grams; (3) fruit weighing from 55 to 70 grams; (4) fruit weighing less than 55 grams. Generally speaking there are from 14 to 16 mandarines to a kilogram.

For the Moscow Agricultural Exhibition to be held during this year, the Trust has organized a competition between the various State, collective and peasant farms, illustrating the progress made in this important branch of fruit production during the last few years.

In this connection, it is interesting to study the publication by KAPTSINEL, M. (Citrus economy. *Soviet Subtropics*, Moscow 1938, No. 7, pp. 13-17), giving details of the area, production and gross profits obtained by the best sovkhos and kolkhos, a part of whose cultivated area is given over to citrus cultivation. This document brings out the wide differences in yield per cultivated hectare, and the very considerable difference in the selling prices of the fruits produced by the various enterprises participating in the Moscow Agricultural Exhibition. In the Kohorsky sovkhos (Galsky district, Abkhazia) founded in 1931, 3,235,000 fruits were produced in 1937 and sold for the sum of 995,000 roubles, while in the Kalinine kolkhos (Kobulety district), founded in 1929, the 1937 production amounted to 679,000 fruits which sold for 759,000 roubles. The ratio between the prices obtained for their fruits by these two concerns was therefore 0.8 to 3.3, or, in other words, the sale price varied between 0.31 roubles apiece for fruit grown at the Kohorsky sovkhos and 1.1 roubles apiece for the Kalinine fruit.

The following are the principal enemies of citrus fruits: *Pseudococcus gahani* Gren, *Pulvinaria aurantii* Ckll., *Lepidosaphes gloveri* Pack., *Ceroplastes sinensis* Dlg., *Aspidiotus perniciosus* Comst., *Aonidiella citrina* Coq.

A study of the Russian publications of the last few years dealing with citrus cultivation does not give a very clear idea of the real situation or of the prospects, as information and statistics are often incomplete, inexact and contradictory. It is clear, however, that a great effort has been made during the last ten years to develop citrus fruit production, formerly almost unknown in the country, and that encouraging results have been obtained.

A. PASCUAL.

## SOME LONCHOCARPUS SPECIES, ROTENONE YIELDING PLANTS OF SOUTH AMERICA (*concluded*)

### III. — Uses.

#### TOXICITY AND BIOLOGICAL EFFECTS OF PREPARATIONS WITH CUBE POWDER.

##### (a) EFFECTS ON HIGHER ORGANISMS.

Many of the insecticides now in use contain certain substances which are very poisonous for human beings and for farm animals. Investigations have been made by a number of writers as to the biological action on the higher organisms of cubé powder and of preparations with a cubé powder basis. The results obtained show that rotenone appears to be only slightly poisonous for the higher animals; the effects of tephrosin, deguelin and toxicarol are trifling, at least when administered by the mouth. According to ROARK, fruits sprayed with rotenone preparations have no poisonous effects on human beings, from the day after the spraying. *Insecticides on a basis of rotenone or of the associated principles may thus be considered as practically harmless for human beings.*

Certain precautions should, however, be taken when crushing the roots. J. VINAS says that the crushing of roots and the preparation of rotenone insecticides involve for the workers certain disagreeable consequences, such as irritation of the throat, inflammation of the skin, blepharitis and conjunctivitis. Actual toxic effects are not known even after weeks of work. To avoid these drawbacks it is advisable to get rid of all dust, and to ventilate premises carefully and to oblige workers to wear spectacles and a mask consisting of a sponge which is kept damp in a rubber container.

##### (b) EFFECTS ON THE LOWER ANIMALS.

According to the historical survey made by ROARK the toxic substances from cubé were first employed in Surinam at the beginning of 1919 on the ant *Dolichoderus bidens* (Latr.). The results were doubtful.

The first really scientific trials on the utilization of cubé in agriculture were carried out in 1924 by MM. INDRO and SIEVERS. Later a number of investigations were made by other entomologists on the toxic effects of rotenone insecticides on the lower animals and on insects in particular. This toxicity varies greatly between different groups.

In any case, the action of rotenone insecticides is made much more effective by the addition of solvents or emulsions. In this way a better contact with the insects is effected and the fats with which their bodies are covered are dissolved. As rotenone is most often used as an external poison, the addition of all substances assisting the action of such poisons (in particular the sulphonate and oxide derivatives of petrol hydrocarbides) will greatly increase the efficacy of

rotenone insecticides. Finally it has been observed that the addition of soap emulsion increased the toxicity of insecticides with a cubé basis.

The results obtained in the course of toxicity experiments are briefly reported here.

#### *Orthoptera.*

The orthoptera appear to resist rotenone fairly well, as application is difficult. FRAPPA has however succeeded in obtaining good results in the case of house crickets, using commercial cubé powder.

#### *Hemiptera.*

Plant lice and, generally, all insects with soft non-protective teguments are very susceptible to the action of preparations with a basis of rotenone and associated principles. The relative toxicity of the different constituents of cubé roots may be estimated approximately as follows: rotenone = 400; deguelin = 40; tephrosin = 10; toxicarol = 1. The results obtained by experimenters show that rotenone at a strength of 1/100,000 compares favourably with nicotine at 1/10,000 and with the pyrethrins at 1/74,800.

The Aleurodidae are nearly as vulnerable as the plant lice. On the other hand, the scale insects, except for the pseudococci, resist the action of rotenone well.

#### *Coleoptera.*

No positive result in control of weevils has been obtained with rotenone. The larvae of the Chrysomelidae have been successfully kept down, a 96 per cent. mortality having been achieved with the larvae of the potato Colorado beetle (*Leptinotarsa decemlineata*). Results with the fully developed insect are less satisfactory. It is considered by DAVIDSON that, for destroying the larvae and eggs of the Colorado beetle, application of insecticides containing rotenone in a proportion of 1/120,000 might well replace those on a basis of 2 per cent. of lead arseniate, as generally applied.

The Coccinellidae, both fully developed insects and larvae, and in particular *Epilachna corrupta* Muls., are easily destroyed with sufficiently strong solutions.

#### *Lepidoptera.*

Trials have shown that against certain kinds of caterpillars rotenone is more effective than nicotine. It acts, in this case, not only as an external insecticide but even more as an internal poison. Rotenone and the associated principles are classed as internal poisons in the same order when used as external insecticides, while lead arseniate is placed, for toxicity, between tephrosin and toxicarol. On the whole however cubé has been shown to be ineffective against Lepidoptera.

*Diptera.*

The Diptera seem to be very susceptible to the action of rotenone and the associated principles, even when applied in very dilute solutions.

J. E. WILLE, J. ALCIDES OCAMPO, A. WEBERBAUER and D. SCHOFIELD, after comprehensive enquiry into the subject, reach the following conclusions:

(1) According to publications in all parts of the world, insecticides with a basis of rotenone and associated principles are effective against the different aphides. They have a limited effect on the Coleoptera and the Lepidoptera.

(2) These insecticides are not suitable for use against the Coccidae, the Coleoptera and the Lepidoptera in general.

(3) Experiments made by the Department of Entomology of La Molina Experiment Station have shown that insecticides with a basis of rotenone and the associated principles have been fairly efficacious against *Aphis gossypii*, very slightly efficacious and only in very high, and consequently uneconomic, concentrations, against *Dysdercus ruficollis* in laboratory trials, and completely inefficacious in field trials.

It appears from these results that it is difficult to utilize insecticides with a cubé basis for destruction of the insects most harmful to agriculture.

*Comparative toxicity of cubé and Derris insecticides.*

Since the most important active principle in insecticides with a cubé basis and those with a *Derris* basis is *rotenone*, it was of interest to see if the preparations with equal concentrations of rotenone had equal insecticide efficacy. Experiments were accordingly undertaken by P. A. van der LAAN and C. M. L. SMULDERS on the relative toxicity of preparations on a cubé and on a *Derris* basis, having the same rotenone content. The results of their trials were that preparations on a cubé basis were always less effective than those on a *Derris* basis (with equal rotenone content).

In their investigations these entomologists employed 8 types of *Derris* and *Lonchocarpus* powders which they used to prepare insecticides with the same rotenone content. The rotenone contents selected were in percentages of  $\frac{1}{2}$ ,  $\frac{3}{4}$  and 1, and the powders were mixed in suitable proportions with neutral substances, kieselgur, for example. The observations related to 120 insects belonging to the following species: *Euproctis chrysorrhoea* L., *Lophyrus pini* L. and *Myrmica rubra* L.

The results appear in Table III.

The following conclusions may be drawn from inspection of Table III: (1) Preparations on a *Derris* basis have on the average a greater efficacy against insects than those on a *Lonchocarpus* basis. (2) On caterpillars of *Euproctis chrysorrhoea* and on the larvae of *Lophyrus pini*, *Derris* preparations have almost double the efficacy of *Lonchocarpus* preparations. (3) *Derris* preparation are twice as efficacious against ants as *Lonchocarpus* preparations. *Derris* preparations with 0.5 per cent. rotenone content are even more efficacious than *Lonchocarpus* preparations with 1 per cent. rotenone content.

TABLE III. — *Comparative effect of insecticides on basis of Lonchocarpus or Derris powders with the same rotenone content.*

(according to experiments made by P. A. van der LAAN and C. M. L. SMULDERS).

Insects	Derris		Lonchocarpus	
	rotenone content %	average % of insects killed	rotenone content %	average % of insects killed
<i>Euproctis chrysorrhæa</i> L. . . . .	$\frac{3}{4}$	37.9	$\frac{3}{4}$	26.4
<i>Lophyrus pini</i> L. . . . .	$\frac{1}{2}$	53.1	$\frac{1}{2}$	42.1
<i>Myrmica rubra</i> L. . . . .	$\frac{1}{2}$	37.5	$\frac{1}{2}$	17.7
	$\frac{3}{4}$	59.5	$\frac{3}{4}$	28.5
	I	69.4	I	37.5

## (c) EFFECT ON PARASITES OF FARM ANIMALS.

Preparations with a basis of *Lonchocarpus* powders are frequently used in Peru for the preparation of antiparasitic dips for sheep and cattle. According to the trials made on the Chuquibambilla farm in Peru, by H. PRESTON and C. J. BILLIWILLER, the following preparation has been established as the most efficacious: 227 grammes of pulverised cubé roots, containing at least 5 per cent. of rotenone to 100 gallons or 378.5 litres of water. For very severe cases, the proportion of cubé should be doubled.

Dr. J. F. MITCHELL of the Junín Central Stock Breeding Society recommends the following concentrations (see Table IV) as effective against the chief parasites of farm animals.

From the results obtained, there can be no doubt that cubé preparations will be increasingly employed for antiparasitic dips.

TABLE IV. — *Concentrations recommended for antiparasitic dips by J. F. MITCHELL of the Central Stock Breeding Society of Junín.*

Preparations and concentrations utilized		Sheep tick <i>Melophagus</i> <i>ovinus</i>	Cattle louse <i>Haematopinus</i> <i>eurysternus</i>	Goat mange <i>Sarcoptes</i> <i>sp.</i>	Alpaca mange <i>Psoroptes</i> <i>sp.</i>	Pig louse <i>Haematopinus</i> <i>suis</i>

	% of rotenone	0.00064	0.00038	0.00129	0.00129	0.00076

(d) HOUSEHOLD USES.

Cubé and its various preparations may be utilized against lice and other parasites on man, against house pests (flies, mosquitoes, bugs, etc.) and against insects which attack foodstuffs.

The Maldonado Laboratory at Lima in 1931 prepared two products known as Sarnol and Piojol which both contain cubé extracts and have proved very efficacious against scabies in human beings. The effect is noticeable from the first application.

For destroying cockroaches, trials have been made with good results of a mixture consisting of 9 parts of potato starch and one part of *Derriis* or cubé powder with 5 per cent. rotenone content.

Preliminary trials made by the Department of Entomology of La Molina Experiment Station have given the impression that cubé roots with 5 per cent. content in rotenone, killing fish in 30 minutes, have no effect on mosquito larvae (*Anopheles pseudopunctipennis*). Similarly cubé powders have proved ineffective against bugs.

Trials carried out with cubé extracts diluted in kerosene have shown that these preparations were very effective against house flies and mosquitoes.

TRADE AND PRICES.

It is only within the last few years that the roots or powders of *Lonchocarpus* have entered into trade. It may be said that before 1932 cubé was not known in South America, except in certain parts of Peru where it was used for fishing. The first exports of cubé came from Surinam. SPOON mentions in an article that in 1930 more than 6,000 kg. of "nekoe" were already being exported from Surinam. After very wide fluctuations the volume of these exports was fixed again in 1932 at about 6,000 kg. as initial quantity.

Exports from Brazil only began in 1933 and on a somewhat limited scale; subsequently they were continued and in 1934—the last figure known—they amounted to 25 m. tons. The price paid was 480 milreis per metric ton f. o. b. Belem (Pará). The chief exporting port in Brazil is Pará. In view of the efforts made by the Brazilian Government to develop the cultivation and exploitation of timbó, Brazilian exports will undoubtedly increase and will occupy an important position on the world market.

At the present time, Peru is by far the leading exporter of cubé. Exports began in 1932 and the principal importing countries are the United States, Germany, France and Great Britain.

In Table V is shown the volume of exports from 1932 to the first seven months of 1938, under the principal importing countries, (for the first seven months of 1938 the figure shown is the aggregate quantity), and the corresponding value of exports in gold francs. The figures are those published in the Yearbook of Foreign Trade of Peru; the total values of the exports given in this Yearbook in "gold Soles", the Peruvian currency, have been converted

TABLE V. — *Volume and value of exports*

Countries	1932		1933		1934	
	Kg.	Gold francs	Kg.	Gold francs	Kg.	Gold francs
Germany . . . . .	78	16.80	104	46.52	3,418	967.40
Australia . . . . .	—	—	—	—	—	—
Belgium . . . . .	—	—	—	—	—	—
United States . . . . .	5,414	1,355.10	9,761	3,610.67	227,297	68,819.40
France . . . . .	428	86.42	1,724	659 —	4,643	1,302.13
Great Britain . . . . .	1,105	484.91	4,493	1,386.24	19,307	5,641.3
Netherlands . . . . .	—	—	—	—	—	—
Italy . . . . .	—	—	—	—	—	—
Sweden . . . . .	676	1,200.27	—	—	—	—
Other countries . . . . .	—	—	—	—	—	—
Total . . .	7,701	3,143.50	16,082	5,702.33	254,665	76,730.23

into gold francs using the successive devaluation coefficients published in the Statistical Yearbook of the League of Nations.

From this Table it will be seen that there has been a very large increase in the Peruvian exports which have risen, in five years, from 7,701 to 393,870 kg. It will also be noted that this rapid development of the Peruvian exports of *Lonchocarpus* roots was mainly effected in three years, from 1932 to 1935. Since then the fluctuations in volume have been much less marked, after reaching a maximum in 1935. From the figure of exports in the first 7 months of 1938 (249,852 kg.) it may be presumed that the maximum of 1935 will be exceeded in 1938 or at least reached.

It is of interest to note that the trends of development of exports the leading countries of destination—the United States, France, Great Britain and Germany—differ very markedly in each case. In the United States, a steep rise in exports was followed by a sharp fall and then by a fresh increase. In France and in Great Britain on the other hand a steady rise is observed up to 1935 and 1936, followed by a perceptible decline in 1937. In Germany there was a very decided rise in the course of 1934, after which exports seem to be practically stabilized. These fluctuations are shown in the following graph.

from Peru of unmilled *Lonchocarpus* roots.

1935		1936		1937		1938 (first 7 months)

—	—	—	—	16,885	50,463.98	...	...
439,544	192,854.42	361,651	690,703.83	393,870	587,857.84	249,852	...

TABLE VI. — *Proportion of the four leading importing countries in cubé exports from Peru (1).*

Countries	1932	1933	1934	1935	1936	1937
Germany . . . . .	1 %	0.6 %	1.3 %	1.2 %	8.5 %	8.5 %
United States . . . . .	70 %	60 %	89 %	60 %	19 %	50 %
France . . . . .	5.5 %	10 %	1.8 %	14 %	51 %	30 %
Great Britain . . . . .	13 %	29 %	7.9 %	15 %	21 %	4 %

(1) The figures are approximate.

The percentages in this table showing the distribution of cubé exports among the four leading purchasing countries confirm the variations already noted in the graph and reveal that the exports are mainly absorbed by two countries, *viz.* the United States and France.

\*\* *Tec. 2 Engl.*

## PORTS OF EMBARCATION.

Peruvian cubé exports are nearly all made through the port of Iquitos (on the Amazon). The ports of Callao, Eten, Paita and Mollendo also carry on a small export trade in cubé roots.

## PRICES.

The value of cubé roots depends on their rotenone content and varies with this content. Considerable research is now being carried out on the other elements with a view to fixing prices with these also taken into consideration. Prices vary according to ports of embarkation and importing countries. Table VII shows the prices in kilograms of raw roots.

TABLE VII. — *Prices per kg. in gold francs of raw roots of Lonchocarpus according to the different importing countries.*

Countries	1932	1933	1934	1935	1936	1937
Germany . . . . .	0.21	0.44	0.28	0.42	1.27	2.00
United States . . . . .	0.33	0.36	0.30	0.45	1.00	0.91
France . . . . .	0.20	0.38	0.27	0.38	2.57	1.80
Great Britain . . . . .	0.40	0.30	0.29	0.42	1.47	2.50

Table VII has been prepared from the figures given in « gold Soles » in the Yearbooks of the Foreign Trade of Peru; the gold soles have been converted into gold francs using for each year the devaluation coefficients contained in the Statistical Yearbook of the League of Nations.

A study of the table reveals the very noticeable rise in prices from 1932 to 1937; this rise is in part due to the development of demand.

Prices of *Derris* powder are usually slightly higher than those of *Lonchocarpus* powder with the same rotenone content.

## LEGISLATION RELATING TO LONCHOCARPUS.

The Peruvian Government has promulgated a Supreme Decree and three Ministerial Resolutions for the protection of the cubé industry in Peru. A summary of this legislation follows.

(a) Supreme Decree No. 62 (Decreto Supremo No. 62 of April 4, 1933).

(1) The cultivation and industrial exploitation of plants known in the country under the names of barbasco or of cubé are declared to be of public utility.

(2) The sale outside the country of cuttings, seeds and fresh roots of these plants is prohibited.

(3) Export is permitted only of roots containing at most 10 per cent. of water.

(4) Parties concerned must apply to the competent authorities to obtain the certificate of analysis of the products and the export permits.

(5) The Department of Agriculture is empowered to instal central plants for extraction of rotenone in the localities best suited for the purpose.

(6) The Department of Agriculture shall take the necessary measures for the development of the scientific cultivation of the *Lonchocarpus* spp. and for their industrial processing.

The Ministerial Resolutions lay down the procedure to be followed for enabling exporters of cubé by the river port of Iquitos to have samples of their product analysed and to obtain export permits. The rules are also established for the installation of central plants for rotenone extraction.

The Government of the State of Pará in Brazil promulgated on April 3 1934 Decree No. 1259 placing the cultivation, trade and export of timbó under the control of the Department of Agriculture, Industry and Commerce. The only species of timbó that may be cultivated are those known under the names of macaquinho and uruçú. Other kinds may also be utilized but only on condition that they contain more than 3.5 per cent. of the active element. Export of timbó roots of all kinds is prohibited. For export the roots must first be carefully prepared, dried, reduced to powder and packed in tin containers hermetically sealed. Timbó powders can be exported only if accompanied by a certificate stating their water and rotenone content, and only timbó powders containing at least 3.5 per cent. of rotenone may be exported.

*Exports to the leading countries of destination.*

#### SUMMARY.

1. — Of all the fish-poisoning plants belonging to the genus *Lonchocarpus* which grow wild in Central and South America, *Lonchocarpus nicou* is the richest in toxic elements.

2. — *Lonchocarpus* spp. are cultivated mainly in Peru, Brazil, Dutch and British Guiana. They are known under various names: cubé, timbó, nekoe, haiari, etc.

3. — The plants belonging to the genus *Lonchocarpus* prefer a hot moist climate; they adapt themselves to all soils, but prefer light soils. They are best grown in association with other crops; propagation is effected by means of cuttings; the gathering of the roots takes place in the course of the second or third year, when the roots have a maximum content in toxic elements. The yield per hectare of fresh roots may be from 4500 to 4800 kg. The plants are liable to be attacked by certain insects.

4. — For commercial uses the roots must be dried so as not to contain more than 10 per cent. of water, then ground till the powder passes through No. 200 mesh. The roots are usually shipped before grinding, pressed in bales of 100 kg. *Derris* and *Lonchocarpus* powders differ in odour and colour; for identification in mixtures masking these two characteristics, it is necessary to examine them under the microscope, when the two types of starch grains can be distinguished.

5. — *Lonchocarpus* roots contain, as active elements, rotenone, tephrosin, deguelin and toxicarol. Long slender roots have the highest rotenone content. The average rotenone content is 5 per cent. Extracts of these roots can be obtained by means of solvents, the most important of which are acetone and ethylene dichloride. The toxicity of the total extract of *Lonchocarpus* roots does not depend on the solvent utilized, whereas that of the total extract of *Derris* roots does so depend.

6. — Insecticides with a rotenone basis are not poisonous for the higher animals. Their toxicity for the lower animals varies with the different species; it may be greatly increased by the action of solvents or emulsions.

7. — Legislation has been enacted by the producing countries, Peru and Brazil, for the development of *Lonchocarpus* cultivation and for the standardization of the products exported.

## THE IMPORTANCE OF BREED CHARACTERS IN MODERN ANIMAL BREEDING

In a previous paper which appeared in the *Monthly Bulletin of Agricultural Science and Practice* No. 5, May 1937 the importance of the concept of the word «breed» was pointed out. It was also discussed, in that paper, how far breed characters should or should not be considered in the breeding of domestic animals. In view of the great importance of this problem and the disagreement among specialists, the author of this article has sought the opinion of experts of different countries. Although only a few of these opinions could be obtained to date, they offer considerable interest, both to animal husbandry workers and to actual breeders, and are worthy therefore of publication and discussion.

### The significance of the phrase «breed characters».

It appears from the opinions expressed that experts in different countries have varying ideas about what is to be understood by «breed characters».

Prof. BUCHANAN SMITH (Edinburgh) distinguishes two groups of these characters:

- (a) those which possess some obvious economic value;
- (b) those which are merely used to distinguish a breed without contributing to the efficiency of the individual animal as a producer. The latter group is usually designated in Great Britain as «fancy points».

Dr. ENGELER (Lucerne) states that formerly under the term «breed characters» all those qualities of the animal have been considered which are apparent to the eye of the observer, *e.g.*, not only the colour and the pattern, but also the size and the particular form of some part of the animal's body. Only more recently, the concept also comprised, according to Dr. ENGELER, physiological characters not apparent to the eye, including characters of economic importance. ENGELER distinguishes between «properties» and «characters» of a breed, the former term comprising only external morphological characters.

Dr. GRAVES (Washington) includes in the idea of breed characters also physiological properties and characters of economic value like percentage of butter-fat in the milk.

In contrast to these opinions Prof. KRALLINGER (Breslau) understands by breed characters only exterior properties of the animal as colour, form of horns, size etc. (*i.e.*, essentially those characters which are classified by BUCHANAN SMITH in his group (b)).

In order to obtain some uniformity in what in this article will be considered as «breed characters», it should be kept in mind that «breed characters» can be only those which distinguish one breed from another and which are common to all animals within the group considered as a breed. Physiological characters, and particularly those responsible for quality, normally vary very much from one animal to the other within the same breed and are very often common to animals

belonging to different breeds. There may be some exceptions to this general rule, but generally these groups of characters are typical individual characters. Average values of characters have been established for certain breeds and these averages differ from breed to breed.

Whoever may be right in this controversial question of the definition of the term "breed characters", only such characters will be considered, in the following lines, as are covered by group (b) of Prof. BUCHANAN SMITH's classification.

### General advantages attributed to "breed characters".

The opinions expressed seem to agree that the group of characters which Prof. BUCHANAN SMITH calls "fancy points" is given less and less consideration.

According to GRAVES, in the United States very few breed characters are considered in determining the eligibility of an animal for registration in a herd-book, but more emphasis is laid on breeds in the show ring.

ENGELER states that if producing qualities only are included under the term "breed characters" this term still has justification for existence. If the concept is limited to morphological properties it would be quite incomplete and unilateral and sometimes even in contrast to the very scope of practical animal breeding.

KRALLINGER expresses the viewpoint that where modern genetics are applied to animal breeding, all over-emphasized requirements as to breed characters are getting more and more limited and, citing some examples, he concludes that this trend of development seems not yet to be completed.

Even BUCHANAN SMITH, who defends in general the maintenance of breed characters, expresses the view that the importance of such characters have been over-emphasized in the past by some groups of breeders.

The time when great importance was attributed to the external characters of a breed lies thus already far behind us, but still there is no agreement as to how far such characters actually merit consideration.

BUCHANAN SMITH is of the opinion that these characters continue to have a distinct value and he specifies the following advantages in favour of what he calls "fancy points".

(1) "Fancy points" constitute a trade mark for type. This helps the breeder to sell his stock and assists the ordinary farmer in knowing what class of animal he is buying.

(2) In the event of crossing, it makes it possible frequently to analyse the parents of crossbred progeny. This is of particular value in the case of crossbred sheep for mutton production. By identifying the breeds to which the parents of the crossbred sheep belong, the purchaser can make a truer estimate of the carcase.

(3) A uniform type in a breed makes judging definitely easier. Where animals are coloured in a nondescript fashion, judging by the eye becomes more difficult. We agree that eye judgment is not of the supreme importance that it used to be, but we are of opinion that it is still important only in assessing the longevity of the animal.

(4) As the fourth reason, we may state that a breed that has uniformity in its outward appearance gives the same impression as the farm which is tidy.

GRAVES attributes to the breed characters "little or no economic significance other than that may be acquired in bringing about uniformity in the conformation and appearance of a breed".

KRALLINGER and ENGELER do not specify the measure of importance and the advantages they would attribute to these groups of characters. They however clearly recognize the importance of the latter as trade marks and mention that upgrading of breed characters generally coincides with the achievement of a higher standard of economic characters.

As one of the more frequently stressed advantages of the breed characters, their value as a *trade mark* must be discussed. A trade mark in general gives the buyer a certain guarantee as to the content and the intrinsic value of the merchandise he is buying. Do breed characters comply with this requirement? There is no doubt, that the real economic value of an animal is constituted by its producing qualities, either actual or latent, *i. e.*, residing in its germ-plasm transmissible to its offspring. It could not fairly be said, that external breed characters constitute a guarantee or even a limited guarantee for these values. In those cases where external characters can provide an indication of the producing qualities, such characters no longer belong to the group of "fancy points" under consideration.

The second advantage, put forward by Prof. BUCHANAN SMITH, in favour of the "fancy points", is consistent, but applies only to a rather limited group of animals, *i. e.*, to those animals used for *crossbreeding in connection with certain kinds of production*. In these cases, where crossbreeding is used in order to obtain animals particularly fitted for specific purposes as, *e. g.*, the crossbreeding of sheep for mutton production cited by BUCHANAN SMITH, it is still doubtful whether or not it is essential to know the breed of the animals crossed and if it is not, in this case as in many others, a question of the *production type* of the animals concerned. Type, however, is generally common to several breeds and therefore independent of the concept of breed characters. In this respect a statement of GRAVES is very significant: "All of our (American) breed associations have somewhat the same ideal for the conformation of their respective breeds". It seems probable, that the concept of type as given above and that of conformation as understood by GRAVES, cover somewhat the same idea. GRAVES, speaking particularly about dairy cattle, explains: "All of them (breed associations) are emphasizing the quality and shape of the udder and the size and the placement of teats".

It is therefore doubtful, whether the advantage stressed in favour of breed characters does not apply rather to the *type*. But even if there are breed characters useful in crossbreeding for production, these would not belong to the group of characters under consideration, as they would be of "obvious economic importance". Characters of economic importance, as also sex-linked external characters of certain poultry breeds, are exclusively used today for distinguishing males and females at a very early date.

It is also stressed that breed characters render *judging by the eye* easier and that, even if judging by the eye is not of the supreme importance that it used to be, it is still important at least as a means for assessing longevity.

There is no doubt, that conclusions on certain production properties and even on longevity may be drawn by judging the animal by the eye. But this judgment does not concern the group of characters, with which we are concerned here. It is not probable that colour and pattern or the shape of horns has any relation to production or longevity. This judgment by the eye probably applies much more to the characters classified by Prof. BUCHANAN SMITH under his group (a) as, obviously, characters connected with the animal's longevity are also characters of great economic importance.

The fourth point put forward in favour of breed characters is a purely *aesthetic point of view* and is stressed both by BUCHANAN SMITH and by ENGELER. Both compare the importance of these characters with attractive cartons holding merchandise, for which the housewife will pay a higher price than for articles offered in a less attractive form. This point of view is an essentially subjective one, and accordingly lies outside the scope of any objective discussion. It is a question of taste and as there are so many different breeds with so many different external characters within each production type of animals, the choice of characters by the breeders from an aesthetic viewpoint is very wide.

This aesthetic viewpoint will, of course, always maintain its importance and play its part in the choice of a buyer. But whether the importance of breed characters is purely aesthetic or if economic importance is to be attributed to them should be made quite clear.

#### Disadvantages of breed characters.

Several of the disadvantages of taking into account breed characters in modern animal breeding are very clearly pointed out by Prof. BUCHANAN SMITH, who admits that the «more practical person will feel that the disadvantages outweigh the advantages». According to BUCHANAN SMITH the disadvantages are as follows:—

(1) The existence of «fancy points» means that the breeder has more to select for. This, therefore, increases the difficulty of his breeding operations. It is comparatively simple to «fix» one characteristic in the homozygous state. It is more difficult to «fix» two characters simultaneously, and the difficulties increase as the number of characters, for which the breeder has to select increases.

(2) There is a danger that breeders might consider «fancy points» as their main objective, at the expense of the true economy of production.

The first of these two points is certainly of great importance. The main objective of breeding today is to develop the highest possible production without weakening too much the animal's resistance against adverse influences. It is well-known how difficult this task of the breeder is. Both production – even in the case of single purpose animals – and resistance to adverse conditions are controlled by a considerable number of genetic factors. Each additional factor to be selected for limits the number of animals at disposal for selection. Multiplicity of breed characters diminish, therefore, the possibilities of selection for production and resistance, and renders the task of the breeder more difficult than it actually is.

There is no doubt that the second disadvantage mentioned by BUCHANAN SMITH is also of great importance, but there is a third one which should not be neglected, although there is not yet any definite scientific evidence in favour of it.

What are generally called breed characters are very probably the results of the natural selection through many generations carried out in a given environment in which the group of animals, defined as a breed, live. At a time when the breeder did not yet strongly interfere with the development of the domestic animals and when there was less trade and movement of animals from one region to another, the natural environment of each breeding area developed the characters most suited to that environment and fixed them in the germ-plasm of the animals. While this is true in the case of most of the domestic animal breeds, there are some which have developed their characters in more recent times mainly by crossbreeding.

Since the time when natural selection and adaptation of the breeds took place, most of the groups of animals, bearing the characters so developed, have expanded far beyond the limits of their original home and habitat. Modern transportation has also displaced animals to regions far distant from those of their origin. The animals have come to live in environments absolutely different from those which brought about their respective characters. In most cases it is probable that these characters would gradually change in the new environment and that the original characters would be replaced by others more adapted to the new environment. There are many indications to prove such a trend. But this natural modification of characters is strongly opposed by the interference of the breeder who tries to maintain the original characters of the breed.

Among the many examples which could be given in support of this fact, perhaps the most striking is the cattle population of America. The whole American continent contains today, with a few exceptions only, cattle breeds of European origin. Most of these breeds are to be found in America under quite different environmental conditions than those of their native European countries. Herdbooks and breeders do their best to maintain the original colour and the original size of these animals, very often in spite of the continuous degeneration of those characters fostered by environment. A great deal of the effort of these breeders is spent in maintaining the breed characters and therefore in working against natural selection, acting in favour of adaptation. If the final results of this breeding activity are not disastrous, it may be due to the fact that in most of the breeding regions of America, climatic conditions are not extreme and breeders are making great efforts to increase production and maintain resistance against adverse factors.

In all cases where European breeds have been imported and bred in countries with extreme conditions, especially in tropical regions, the result has been a rapid and complete degeneration of original characters. In the majority of such countries, endeavours with European breeds have soon been abandoned. There is no doubt that natural modifications of original characters take place to a lesser extent through a slower development in less extreme conditions if the process is not outweighed by the breeder's efforts to maintain the original breed characters.

It is true that the breeders's efforts must always be in some way in opposition to the action of nature. If the breeder would not interfere at all with that action, the animals would within a number of generations return to some primitive type with consequent low production. But this interference with natural selection by the breeder should be limited to the characters which are really essential to the breeder's aim. The breeder should as little as possible impede the acclimatization of the animal to the conditions where the animal has to live. He should leave to nature the task of selecting the colour, the horns and the size which are most fitted for the respective environment. There is little doubt that this would be very much in favour of health and resistance against adverse factors and would reduce the breeders' efforts to maintain these properties by selection and facilitate their task to increase production.

It may be concluded that the views expressed by some authorities in animal breeding matters do not permit any final statement on the question put forward. Some advantages of breed characters are counterbalanced by some disadvantages. The problem, therefore, remains open to further discussion. There may be other advantages or disadvantages which have not yet been mentioned. The author of the present article will be glad to publish in this Bulletin any authoritative opinion which may contribute to solve this important and controversial question.

ST. TAUSSIG.

## AGRICULTURAL SERVICES SUPPLIED BY RAILWAY COMPANIES (*continued*)

### United States.

For many years the railway companies of the United States have carried on propaganda by means of agricultural trains or agricultural cars carrying educational material and speakers, usually in cooperation with the State Extension Services.

There has been no systematic development of agricultural trains in the United States, their use depending largely on the desire of a particular railroad to develop some phase of agriculture in the territory it serves. The general practice has been for the railroad to furnish the equipment and operate the train with the State Extension Service furnishing the exhibit material and speakers. With this policy there is, of course, no danger that enthusiastic railroad development agents will urge undue expansion in some line of agricultural production which the research and extension workers at the State Colleges believe to be unsound. Four railroads, serving different sections of the country, operate agricultural trains. The Northern Pacific operates from Minnesota westward to the Pacific coast in the States lying along the Canadian border: the Illinois Central from Chicago to New Orleans, extending westward from

Chicago through Illinois and Iowa, and southward practically the entire length of the Mississippi valley. The Baltimore and Ohio railroad serves the northeastern States from New York and Washington westward to Chicago and St. Louis. The Missouri Pacific operates from St. Louis westward and south-westward principally in the States of Missouri, Kansas, Arkansas, Oklahoma, Louisiana and Texas.

#### NORTHERN PACIFIC RAILWAY.

As an example of the propagandist activities of the various American railway companies those of the Northern Pacific may be regarded as typical. It has long been engaged in colonization work, which was placed under the charge of a general immigration agent appointed for this purpose about 1880. From time to time other work in the way of agricultural education was carried on, in addition to colonization, by special agricultural agents, by the land department, and sometimes by immigration agents. The agricultural development department, definitely grouping together colonization and agricultural services, was formed after the return of United States railroads to their private owners subsequent to the World War.

The first exhibit trains and cars were operated almost entirely with a view to colonization. During the last 15 or 20 years the object has been the agricultural education of farmers already settled in the territory served by the Northern Pacific line.

ESTABLISHMENT OF AN AGRICULTURAL SERVICE. — An Agricultural Service was established by the governing body of the Northern Pacific Railway Company in 1882.

OBJECT. — The object of the Agricultural Service was originally the encouragement of immigration and colonization. These activities were afterwards merged under the agricultural development department which, as mentioned above, now includes colonization and agricultural service. The aim in colonization is to put good land along the railroad into cultivation and keep it in cultivation. The special function of the agricultural service is propaganda and developing better agriculture within its area, supplementing the work of educational bodies and carrying it further than is possible for them: all with the idea of sustaining and increasing traffic. Both types of activity have worked out satisfactorily.

EXHIBIT TRAINS. — The Company has in the past operated exhibit trains and continues to do so. They are controlled by the agricultural development department. Single exhibit cars were used before 1900, but it was not until 1910 or 1911 that the first special train was introduced.

Trains operate at intervals of not less than two years over the same territory. There is no specified season: it varies in accordance with the type of train used and the subjects presented.

COMPOSITION OF AN EXHIBIT TRAIN. — An exhibit train is composed of from two to four or five coaches and sometimes—when farm machinery is being exhibited—several flat cars. Both special power and power from regular train service is used.

The staff usually consists of about 8 or 10 workers on large trains, including the electrician and caretaker. In addition there are state college or other specialists and the railway company's agricultural agents, who receive visitors to the train and answer questions. The coaches have somewhat the appearance of class-rooms. The seats are removed and false walls built on which are shown photographs, charts and drawings. Narrow tables are sometimes placed under the wall exhibits and along one side for the display of other materials, leaving sufficient space for visitors to move comfortably through the cars in a line.

ACTIVITIES OF THE STAFF. — The exhibit-train staff give lectures and demonstrations and also organise educational cinema displays. Supplementary meetings are sometimes held in local halls part of the day when an exhibit train is stopping in the neighbourhood.

PUBLICITY. — When an exhibit-train is to be operated news stories regarding the project are sent to daily and weekly newspapers, and to the agricultural press in the territory concerned, for three or four weeks in advance. Follow-up stories are written for papers of districts visited by the train or exhibit cars and published after the exhibit day. Posters are prepared, printed and distributed ten days in advance of the exhibit day, serving as a brief but forceful reminder. These are displayed in all public places where farm people are likely to see them. Either self-mailers or letter inserts are printed and mailed to large numbers of farm people, giving further details as to the meetings or exhibits. Country extension agents sometimes do some special advertizing of the exhibit on their own account. Local shopkeepers also avail themselves of an opportunity for advertizing their own wares, offering certain bargains, serving free lunch, etc., on the meeting day.

RESULTS. — Satisfactory results have been obtained, especially from the efforts to call attention to better farming practices. There can be no doubt that the train method of education is effective. The attendance varies from a few hundreds to several thousands, according to the type of meeting, nature of the exhibits, subject matter and territory.

BALTIMORE AND OHIO RAILROAD COMPANY. — This company, like the Northern Pacific, has an agricultural service of experts. It is known as the Agricultural Development Department and its principal efforts are directed towards efficient production, the improvement of agricultural practices, classification according to the United States standards and the improvement of marketing methods.

The operation of exhibit trains plays a relatively very minor part in the activities of the Agricultural Development Department, as there are never more than three during the year, each operating for about two weeks.

It is an interesting and significant fact that one issue of the magazine published by the Baltimore and Ohio Railroad is devoted solely to the Agricultural Department. Below are given the titles of articles contained in this Farm Number, some of which are written by the Company's agents:—

The Farmer and the Railroad.  
The Railroad's Contribution to Drought Sufferers.  
The Log of the B & O Soil Improvement Special.  
A Wormy Pig Will Never Get Big.  
Improving Farm Flocks.  
More Profitable Potato Production in Indiana.  
Alton Soybean Program aids Missouri Farmers.  
Production Bred Sires Bring Profit to Dairy Farmers.  
Better Beef Production.  
Indiana Muck Crops Program is Effective.  
Making the West Virginia Market Lamb Supreme.  
Soil Erosion.  
Good Apples Demand Good Packing.

A brief account of the special trains operated by the Baltimore and Ohio Company may be of interest. The most important were the following:

**SOIL IMPROVEMENT SPECIAL.** — This train was organized in cooperation with the State Agricultural Extension Service. Its object was to convince farmers of the value of lime. Several railroad passenger coaches were specially equipped, one as a soils-testing laboratory and lecture car, and the staff was composed chiefly of "soil doctors". In five days over 1000 soil samples were tested and written prescriptions given to the respective owners. Most of the soils needed lime and as each farmer was presented with the prescription he was invited to back his wagon or truck up to the train where he received, free of charge, enough liming material to conduct his own experiment.

The result was that within six years the tonnage of agricultural lime over the Baltimore and Ohio railroad was quadrupled.

**SWINE SANITATION SPECIAL.** — This train was operated by the B & O in cooperation with Ohio State and Purdue Universities through Southwestern Ohio and Central Indiana, 1927-28. It consisted of six coaches, including exhibit and lecture cars. In one car were two families of pigs (17 in all) forming a striking contrast, one being a model family fed on wholesome litter, free from worms and therefore fat and strong, while the other—reared on litter not approved by experts—were small and puny.

The technical aspect of pig-breeding and rearing was presented by experts of Ohio State.

**POULTRY IMPROVEMENT SPECIAL.** — This train was operated in collaboration with the Universities of Maryland, West Virginia and Illinois and the United States Department of Agriculture. It traversed the States of Maryland, West Virginia and Illinois.

This travelling poultry school, offering a full day's programme at each stop, included lectures on the important phases of profitable poultry production, and demonstrations of the means of identifying diseases common to poultry.

The "poultry improvement special" led to the formation of a large number of poultry clubs.

**PUREBRED DAIRY SIRE SPECIAL.** — The first Purebred Dairy Sire Special was operated by the Baltimore and Ohio Railroad over their Southern Indiana lines in September, 1923, when 46 purebred dairy sires were placed and an almost equal number of scrub or grade bulls removed from service. This train has since covered B & O territory in Indiana, Illinois, Ohio, West Virginia, Pennsylvania and Maryland, placing a total of 428 purebred dairy sires and 72 purebred heifers.

Prior to the operation of the Special, several weeks of preliminary work were spent in the counties to be visited, interviewing County Extension Agents, securing the cooperation of bankers, chambers of commerce, service clubs and creamery interests. The object of these activities was to bring to the farmers' attention the purpose of the train and the opportunity which was offered them of disposing of their scrub sires at beef prices when purchasing a purebred bull.

The success of this train was largely due to the cooperation of the Agricultural Extension Service in the states involved, the Dairy Cattle Breed Associations, National Dairy Council, farm papers, local business organizations and interested dairy farmers.

**BETTER BEEF SPECIAL.** — In April 1927 a Better Beef Special was operated through Western Maryland and the Shenandoah Valley of Virginia, in cooperation with the University of Maryland, the Virginia Polytechnic Institute, the Beef Breeders' Association and the National Livestock and Meat Board.

Since the main purpose of the train was to stimulate interest in the production of higher quality market cattle, one of the cars contained purebred Angus, Shorthorn and Hereford bulls.

A feature of the train was the women's lecture car, in which a woman member of the National Live Stock and Meat Board, assisted by State Home Demonstration Agents, dealt with the proper preparation of different cuts of meat.

In connection with the campaign for better beef production mention should be made of the 4-H Beef Club, organized in 1931 under the auspices of the B & O.

**CONCLUSION.** — Railway companies in the United States are privately owned and for the realization of their agricultural programme, therefore, require the support and cooperation of the interested States and the Federal Government—which has always been given. Farming has always been closely linked with the colonization movement and, consequently, with the growth of the railways.

The railway agricultural services are extremely active since each company has to contend with severe road competition and bases its policy on the

principle that the prosperity of a railway depends on the prosperity of the farmers who are served by it.

Railway agricultural propaganda has for its object the establishment of that system of farming most suitable for the rural communities along its lines. Dairy trains, soil improvement trains and pure-bred dairy sire trains; marketing of rams; demonstrations of the grading of livestock; model poultry-yards; establishment of "potato" and "calf" clubs; education of farm boys and girls:— all these are means to one end, the permanent establishment of an improved system of farming.

### Yugoslavia.

RAILWAYS. — Transport in Yugoslavia is to a large extent by railway. When the railways were constructed the conformation of the land had to be taken into account, but the lines were laid as far as possible in accordance with the requirements of the time. Both as regards routes and distribution they are inadequate for present needs.

As is usual in mountainous countries, the proportionate mileage is low, the average being 1 km. of railway to 25<sup>2</sup> km. of territory. The ratio between number of inhabitants and length of railway is high. The greatest defect lies in the disproportion between the various regions:— in Voivodina, for instance, there are nearly 12 km. of railway per ha., in Slavonia 7, in Croatia 4, and in the other parts of the country only 2. In the neighbourhood of the German and Hungarian frontiers there is a closer network, connecting the principal towns with Vienna and Budapest.

Since the formation of the new Kingdom a great effort has been made to link together the various sections of the railway. A glance at a railway map of Yugoslavia will show that there are still very few lines in Serbia and Bosnia and that the interior of the country is not connected with the Adriatic ports, in spite of the fact that exports are for the most part directed towards these.

One of the greatest obstacles to the development of traffic between different parts of the country—even where there is most scope for the development of such traffic—is the existence of different gauges, which necessitates the transshipment of goods.

The steep hill-slopes, the numerous bridges and viaducts, and the sharp curves necessitated by the formation of the land, all combine to involve high maintenance cost and fuel consumption.

The most serious problems confronting the new regime are the readaptation of staff and material to the needs of the country, and the linking up of the various lines.

AGRICULTURAL SERVICES. — In 1932 the General Railway Board of the Kingdom of Yugoslavia set up an Agricultural Service which, after undergoing various changes, continues to function as a section of the Railways Administration.

OBJECTS. — The principal activity of the Agricultural Service is propaganda in districts traversed by the railways. Some of its aims are purely technical, and others of a more general nature.

The most urgent technical problem for the Service is the utilization of lands near the railway.

The work of the Service consists in:—

(1) Making known the existence of cultivable land near the railways and suggesting methods by which it may be most advantageously utilized.

(2) Testing and grading the soils.

(3) Destroying and preventing weeds along the railway line and on model farms.

(4) Draining marshy land, especially by the planting of suitable crops, particularly in ditches flanking the railway lines. Improving such land when drained.

(5) Planting selected fruit trees along the line, and near stations or railway premises. The choice of trees depends upon the natural conditions of the country and the demand of local and foreign markets. They are planted for the double purpose of increasing fruit production and the tonnage carried by the railway.

(6) Forming plantations to screen railway premises of all kinds.

(7) Forming plantations beyond the ditches flanking the line, or on the embankments, for the purpose of retaining the soil in position and preventing the accumulation of masses of snow by the interposition of natural obstacles.

(8) Forming plantations to serve as natural barriers either to prevent access to the line or to mark the boundary between land belonging to the Railway and that of private owners: such plantations always superseding wooden or iron fencing, the upkeep of which costs annually several hundreds of thousands of dinars.

(9) Planting trees, bushes and other melliferous plants for the development of apiculture.

(10) Establishing nurseries for the production of the plants required; breeding in their vicinity bees and poultry which can be utilized as propaganda in favour of apiculture and aviculture for railway employees and by the latter as propaganda for the farmers and peasants. Booklets of instructions are distributed free of charge.

(11) Establishing hothouses and selecting decorative designs for station gardens.

The activities of the Agricultural Services include also both direct and indirect propaganda for farmers. These will be described later.

WORK OF THE AGRICULTURAL SERVICE. — To give some idea of the work of the Service we supply a brief account of what was accomplished between 1931 and April 1, 1938.

PLANTATION OF FRUIT TREES. — Since 1931 fruit trees to the number of 230,000 have been planted in the 48 sections of all the regional divisions. According to the station-masters' reports, and judging also from inspections

of the fruit trees planted, it appears that about 85 % took root. The losses are due to trees being broken by the wind, broken down by heavy snow, burned by fires resulting from over-dry grass, or gnawed by animals.

At first a large number of fruit-trees were stolen. The authorities of the Banats were requested to take measures for the recovery of the trees and, if the thieves were not found, to reimburse the Agricultural Service at the expense of the commune in which the theft was committed. All the trees were bought from the nurseries of the Banats except a very few from private persons, and then only on condition that the same prices were charged. Since 1935 the trees have been obtained from the railway nurseries.

The care of the trees and the spraying against disease and pests serve as practical demonstrations to both railway employees and farmers, being accompanied by explanations as to the use of the brush, preparation of the mixture, etc. The importance of the campaign against insect pests and plant-diseases is made clear.

In some sections brushes are distributed. All are given the necessary chemicals, with written instructions. Saws, knives and shears are distributed free of charge by the Ministry of Agriculture to all the plantation staffs of the five divisions.

This practical propaganda has already produced satisfactory results among agriculturists living near the railway.

**NURSERIES.** — The railway authorities have long realized the necessity of having their own nurseries:—

(1) It was very difficult to procure fruit-trees and 30 or 40 different nurseries had to be dealt with, making it impossible for the representatives of the Agricultural Service to superintend the purchases. In spite of all complaints, therefore, the trees acquired were often of poor quality.

(2) The trees were frequently not of the variety indicated by their labels.

(3) There was a definite shortage of varieties which the Railway Department specially desired to propagate, as being required by foreign purchasers and resistant to long journeys.

Two nurseries of a total area of 5.5 ha., have been formed, one at the station of Mala-Krsna and the other at Batajnica. In addition to fruit trees, they supply melliferous and ornamental trees and bushes which serve a variety of purposes, viz., "camouflage", strengthening slopes, reafforestation, defence against snow drifts, the formation of natural barriers in place of the wooden or iron fencing formerly in use, etc. The number of trees in these nurseries in 1937 was:—

(a) at Mala Krsna:

13,000 fruit trees,

27,000 ornamental trees and bushes;

(b) at Batajnica:—

7,000 fruit trees,

150,000 ornamental trees and bushes.

In 1937 a hothouse was built at Batajnica for the production of roses and *Ampelopsis vaicii* to screen railway stations.

For the strengthening of slopes and for reafforestation the land belonging to the five divisions of the Railway Department has been planted with 1,329,000 plants.

**POULTRY-KEEPING.** — The Agricultural Service is working to improve poultry-breeding, which occupies an important place on Yugoslav farms, while the transport of eggs and poultry is a source of large profits to the railway.

During the last few years there has been a continuous falling-off in the export of these products. This is not due to any decrease in demand but to the fact that the unstandardized Yugoslav products cannot compete with those of Bulgaria, where standardization is compulsory.

The Agricultural Service's campaign is carried on through the medium of the railway staff.

Pamphlets are distributed giving instructions as to the hatching of eggs, breeding and preserving of poultry, improvement of breeds, etc.

The Ministry of Agriculture has shown its sense of the importance of the campaign and the excellent results obtained through the efforts of the railway staff by distributing through the agricultural service, during the years 1933-37, nearly 500 nests of pure-bred poultry, each nest containing one male and three female birds.

The distribution of eggs by the railway employees has led in many regions to an improvement in the breed, as purebred birds were thus obtained. At the International Poultry Show held at Belgrade in 1936 the railway employees had a special pavilion.

Out of the 232 cages exhibited, 192—*i. e.*, nearly 80 per cent.—were awarded prizes.

These successes due to the activities of the railway employees testify to the soundness of the method; for the object in view to be fully attained, however, these efforts must be continued for many years, and on a larger scale.

**APICULTURE.** — In spite of favourable general conditions beekeeping is not much developed in Yugoslavia. The Agricultural Service has therefore begun a campaign on behalf of scientific apiculture.

Cooperative apicultural associations have been formed, having a total membership of 1000, with 10,000 modern hives, and for the last two years apiculture has been making definite progress.

The last Slav Apicultural Show, held at Belgrade, proved that the railway employees were excellent apiculturists. Special articles appeared in both the Yugoslav and foreign press in which they were highly commended.

There are courses of public instruction for railway employees, by arrangement with the Serbian Apicultural Society.

## METHODS OF ACTION.

*Direct Propaganda.*

If by direct propaganda is meant personal contact between the agents of the Agricultural Service (engineers, etc.) and the farmers, the Service does not attach great importance to this. The formation of model holdings along the railway and the various plantations mentioned above are however a form of direct propaganda.

*Indirect propaganda.*

This is the method mainly employed. The Agricultural Service uses the railway employees as propaganda agents, the instruction given to them filtering through fairly rapidly to the rural classes as a whole. This system is most effective. The subjects in which they are instructed have already been mentioned; we will now describe the manner in which the instruction is given.

EXHIBIT TRAINS. — The Railway Administration instituted an exhibit train which operated throughout the country from 1931 to 1933, under the joint authority of the Ministries of Communications and of Agriculture. It was then decided that propaganda should be on a smaller scale, only one special coach being used.

This Agricultural Service coach operates throughout the year for about 6 to 10 days a month, especially at the periods when fruit is packed and loaded on the trains. The interior of the coach is arranged like a school. It is attached to passenger or goods trains. The staff of this instruction course consists of an agricultural engineer from the Railway Administration and two assistants, both of whom are experts.

The interior of the coach forms a large room with two entrances, capable of seating 45 persons. At one end are a lecturer's desk, a blackboard, and various prints and charts illustrating the subjects of the lectures. There are a toilet-room, an office and a gas-stove, heating arrangements, etc.

Instruction is given either in this coach or—if the audience is too large—in station waiting-rooms—or in any convenient place: garden, orchard, apiary, poultry-yard, etc.

Not only railway employees but schools and various local organizations are notified in advance of the arrival of the instruction coach.

The success obtained has been remarkable. The number of listeners (varying between 15 and 250) make it possible to discuss technical subjects with excellent results. Instruction is given twice a day, morning and afternoon.

So far 96 stations have been visited by this instruction coach.

In 1935 the Falcon (Sokol) Association of the Kingdom of Yugoslavia approached the Minister of Communications offering its collaboration. The offer was accepted and members of the Association, both singly and in groups, were

present at the first of the instruction given; some travelled from 25 to 30 km. in order to attend.

The instructions were mimeographed and distributed free among the audience.

FRUIT COACH. — Foreign markets for Yugoslavian fruit were being lost owing to the irregularity of the picking and the unsatisfactory packing. The Agricultural Service decided on a campaign concerning the different operations of this nature, such as the gathering and handling of fruit.

The help of experts from the Central Hygiene Institute was obtained and during the year 1933 the Fruit Coach visited, in the Belgrade Division, 24 of the principal stations for fruit exports on the normal-gauge line and 12 stations on the narrow gauge line, in the Sarajevo Division. A special coach was provided, containing all that was necessary for demonstrations of gathering, sorting and scientific packing of fruit. All necessary explanations were given to the growers and practical demonstrations were made.

A striking feature was the rapidity with which the growers applied their newly acquired knowledge. The attention of the peasants was specially drawn to their mistakes not only in the mode of gathering the fruit but in taking it from the orchard to the station already packed. In this connection pamphlets issued by the Agricultural Service and booklets prepared by the Central Hygiene Institute and the Serbian Agricultural Society were distributed.

The best growers received implements for fruit-gathering intended to serve as models and facilitate demonstrations.

This propaganda campaign showed the necessity of premises in which fruit could be protected from sun, dust and rain during the time between arrival at the stations and loading on the train.

AGRICULTURAL INSTRUCTION AT THE RAILWAY SCHOOL AND INSPECTORS' COURSES. — A word may be added regarding the agricultural instruction given to railway employees.

The Ministry of Agriculture attaches the utmost importance to the agricultural instruction given at the Railway School and at inspectors' courses. It has issued a large number of agricultural publications for distribution among those who attend either the school or the classes.

CONCLUSION. — The establishment of an Agricultural Service by the railways of the Kingdom of Yugoslavia has undoubtedly had a great influence on the agriculture of that country. The propaganda carried on by the railway employees has achieved its object, and has diffused among the agricultural classes new ideas which will enable them better to adjust their production to requirements and will help to promote that better "orientation" of agriculture, which is a problem of the first importance for every country.

*(To be continued)*

A. BOUSSINGAULT.

## MISCELLANEOUS INFORMATION

THE PROGRESS OF AGRICULTURAL SCIENCE IN INDIA DURING THE PAST TWENTY-FIVE YEARS. — This historical sketch of Indian agriculture during the past twenty-five years, has been published by the Indian Science Congress Association (Calcutta, 1938). It will be valued by all those interested in agricultural history. The origins of the Provincial Departments of Agriculture, the Agricultural Research Institute, Pusa (now at New Delhi), the Indian Central Cotton Committee, the Imperial Council of Agricultural Research, the Indian Central Jute, India Lac and Coffee Cess Committees are described, and the part these organizations play in guiding and financing agricultural research. This is followed by an outline of the advances made in India in the various branches of agricultural science particularly in plant breeding, crop diseases and pests, agricultural chemistry, agricultural engineering, statistics in relation to agricultural experiments, etc. It is not possible here even to summarise the principal achievements of workers in the different parts of India, but it may be said that due recognition is given to their contributions, which are increasing in number and in ever wider fields. Recent history is notoriously difficult to write but the author, Dr. W. BURNS, admirably summarizes the main trends of progress and also — thanks to his long experience of Indian conditions, and his clear and comprehensive vision — is able to make some forecasts of scientific and practical importance. The most valuable of these regards the large-scale organization of effective propaganda machinery, and of agricultural economics, with a view to showing how the lot — physical and spiritual — of the cultivator may be improved and the full benefit of scientific investigation made available to him.

G. T. K.

CEREAL SELECTION IN TUNISIA. — In the *Bulletin du Service de l'Agriculture* (Tunis, 2<sup>ème</sup> trimestre 1938, pp. 157-228), the Bureau for Agricultural Experiments and their Popularization in Tunisia publishes a long report on cereal selection and experiments.

### 1. — *Soft wheats.*

Methodical research is being carried out on unimproved native disease-resistant wheats intended to replace the bread wheats now in use (chiefly *Mahon*).

In 1936 and 1937, 161 varieties of soft wheat were introduced from various countries; among these were: *Thatcher*, known for its rust-resisting qualities; *Pusa 120*, also reported as resistant to the various *Puccinia* spp. and an excellent bread wheat; *Gefir*, a strong French wheat, and finally, *Manitoba No. 1*, and *Hard Manitoba*, prototypes of Canadian strong wheats. Hybridization has been directed towards the improvement of baking qualities, productivity and resistance to rust and lodging. The best lines of *Florence* × *Aurora* have been selected for crossing on account of their productivity and their excellent bread-making qualities; other strains selected are *Pusa* × *Florence*, productive and resistant to lodging, *Damiano Chiesa*, famed for its high yield and its short, strong straw, and some Kenya wheats reported as being rust resistant, and several Algerian varieties which have proved satisfactory in Algeria. Two or three strains of *Florence* × *Aurore* have

given remarkable results both in field and Extensimeter test and will be extensively grown by the Botanical and Agrarian Service. The final results of these experiments show that selection with the variety Florence  $\times$  Aurora is still very efficacious, but that, on the contrary, with the Pusa and Florence strains, it is not so, and the majority of lines have therefore been eliminated. The Manitoba, Garnet and Marquis wheats have imparted their strength to their descendents.

## 2. — *Hard wheats.*

Tunisia should be able to produce two groups of hard wheats ripening at different periods, with indigenous or very productive wheats in each group, all disease and rust resisting with light-coloured, translucent grains. Selection as practised at present is directed towards this end.

In 1936 and 1937, forty-eight varieties were introduced from Algeria, Morocco, Greece, Italy, Egypt, Uruguay, etc., for use in cross-breeding with Tunisian late wheats, in order to obtain fixed strains of wheat with the economic qualities and morphological appearance of the parent wheats.

Selection experiments have shown that a single strain of the hybrid M a h m o u d i  $\times$  P y r a m i d a l e 35, No. 209/38/c is suitable for large-scale cultivation, as it grows well and ripens very early, like the earliest soft wheats. The productive qualities and fine appearance of the grain of Palestine wheat No. 847/1 were confirmed: O u e d Z e n a t i especially gives a grain as clear as the B i s k r i breed, but fuller.

## 3. — *Barley.*

In 1936-37, 34 varieties of barley were introduced from Algeria, Poland, Uruguay, Australia, etc. No cross-breeding was practised in 1937, the material collected not being sufficiently studied.

The varieties introduced were pedigreed to obtain homogeneous strains, for the creation of which 150 types were selected. Experiments were made with breeds from M a r t i n barley and two-row barleys introduced during the last few years. So far no definite results have been obtained from the first experiments.

## 4. — *Oats.*

Only one variety was introduced into Algeria and subjected to a preliminary test. Observations were made with 11 varieties kept over from the previous season. Out of 720 strains sown in 1936, 23 were retained.

The Agricultural Service maintains a collection of growing cereals of various species including 300 soft wheats, 245 hard wheats, 58 miscellaneous wheats, 106 barleys and 27 oats.

A. P.

SEVENTH INTERNATIONAL POULTRY CONGRESS. — The 7th International Poultry Congress and Exhibition will be held in Cleveland, Ohio, from July 28 to August 7, 1939.

As in the case of former Congresses, the 7th International Poultry Congress will deal with all branches of poultry and the industries connected therewith. More than 60 countries are expected to participate officially.

G. R.

LEACHING EXPERIMENTS WITH BORATES. — The suitability of water soluble borates (optimum dose corresponding to 4.5 kg. of boric acid per acre, with or without a thinning agent such as sand, fertilizer etc.) for the control of Heart rot of beets and mangolds, Brown rot of swedes and turnups, and other boron deficiency diseases in crop plants, has been investigated at length. Fear has been expressed, however, in certain quarters that the continued use of boron may slowly result in accumulation of the element in the soil and so be harmful. The percolation experiments carried out at the Hamburg Agricultural Experiment Station by C. KRUGEL, C. DEYSPRING and R. LOTHAMMER with seven soil types, using superphosphate mixed with various boron compounds (« Granulated borax », « Borax lime », *Ca-boracite*, etc.), indicate that the residual boron unused by plants amounts approximately to one-fifth of the optimum dose used, and that owing to rainfall, leaching varying between 47 and 94 per cent. occurs in all the seven types. This means that in practice no harmful accumulation of boron is likely to take place.

G. T. K.

XIIth WORLD'S DAIRY CONGRESS, VIENNA, 1940. — At the closing session of the XIth World's Dairy Congress, held in Berlin on August 28th, 1937, a resolution was passed that the next Congress should be held in Vienna in 1940. This resolution was accepted by the German Government and by the President of the International Dairy Federation. The Congress will therefore take place about the end of May or beginning of June, 1940, in Vienna, and will be organised by Herr. R. WALTHER DARRÉ, Reich Minister for Food and Agriculture and Reich Peasant Leader, who will, in due course, issue invitations stating the exact date of the Congress.

*Scientific Subjects.* — The number of subjects discussed will be strictly limited. They have been divided into four sections.

SECTION I. — *Mountain and Alpine Dairying.* — For the first time Section I of the Congress will devote attention to one specific subject. In view of the mountainous character of the Eastmark, Mountain and Alpine Dairying has been chosen. As most of the important dairy countries have mountainous regions, this topic should prove of great interest especially as many problems still remain to be solved.

SECTION II. — *Reports of the International Dairy Federation.* — Section II will be devoted exclusively to the reports of Committees of the International Dairy Federation. In general no papers may be contributed to this section. Suggestions, however, may be made to the chairman of the respective committees who will consider their possible utilisation.

SECTION III. — *Important Questions of General Dairying.* — Section III will deal with questions of importance in General Dairying; with a view to limiting the scientific programme, only two subjects will be discussed.

SECTION IV. — *Tropical Dairying.* — Discussion of the most important problems in tropical dairying, according to the programme of previous congresses. Special topics for discussion will be detailed in this fourth Section.

*Notice of Papers.* — To prevent duplication and overlapping of papers, notice of intended papers must first be given to the National Committee of the International Dairy Federation, stating the section, question to be discussed, and the proposed title of the paper for examination. In case such National Committee does not exist, papers should be sent direct to the Secretary General of the XIIth World's Dairy Congress. With regard to papers from Germany, the Congress Management Committee will communicate direct with the authors.

In any case, notice of papers must reach the office of the Secretary General, XIIth World's Dairy Congress, Hafenplatz 4, Berlin SW 11, not later than February 1, 1939.

*Exhibition.* — An exhibition with special regard to Mountain Dairying and a competition for butter and cheese will be arranged on the occasion of the Congress.

*Excursions.* — In view of the special feature of the Congress, excursions will be made to the mountainous regions of the Ostmark, Bavaria and Sudetenland, etc.

For further details, write to the Secretary General of the XIIth World's Dairy Congress, Hafenplatz 4, Berlin SW 11.

#### *Subjects for Discussion.*

*Section I.* — Mountain and Alpine Dairying: — Topic 1: Mountain Climate and its Influence on Milk Cattle, Milk and Milk Products. — Topic 2: Mountains as a Source of Fodder Supply for the Production of High Quality Milk and Milk Products. — Topic 3: Milk Cattle of the Mountains (Cows, sheep, Goats). — Topic 4: Dairy Husbandry in Mountainous Regions: a) Technical Aspects; b) Business Management.

*Section II.* — Reports of the International Dairy Federation: — 1. Cheese. (Chairman: Dr. A. J. Swaving, Westeinde 58, Voorburg, The Netherlands). — 2. Milk Powder. (Chairman: His Ex. Dr. F. E. Posthuma, The Hague, The Netherlands). — 3. Hygienic Milk Production. (Chairman: Prof. C. Gorini, Città degli Studi, Via Orcagna 4, Milan, Italy). — 4. Technical Aspects of Dairying. (Chairman: His Ex. Dr. F. E. Posthuma, The Hague, The Netherlands). — 5. Special Commission (A) on Production and Central of Milk (Chairman: Ministerialrat Dr. K. Wegener, Wilhelmstrasse, 71, Berlin W 8, Germany). — 6. Special Commission (B) on Standardisation of Bacteriological and Chemical Analysis of Milk Products. (Chairman: prof. R. Burri, Manuelstrasse, 93, Berne, Switzerland). — 7. Other subjects dealt with by the International Dairy Federation.

*Section III.* — Important Questions of General Dairying: — Topic 1: Longkeeping Butter: a) Milk and Cream for Production of Longkeeping Butter: Quality Requirements. b) Technical Aspects of Production, Storage and Transport of Butter. — Topic 2: Reduction of Cost of Dairy Equipment.

*Section IV.* — Tropical Dairying.

E. G.

## BOOK NOTICES \*

SALVADORI, M. *La colonisation européenne au Kénia*, Paris, 1938, 224 pp.

[The problem of European settlement in tropical countries, especially at high altitudes, is one which has to be met by a number of colonising nations. The history of attempts at white settlement in hot countries – attempts which have been made more frequently than is often supposed—deserves therefore the most careful study.

The A. has brought together with great care and complete impartiality all statistics and reports relating to Kenya, where as a British colony the definite establishment of European farmers on the high tablelands was planned from the close of the century. After the world war, more particularly, a large area in the highlands of Kenya was taken up by a number of settlers for coffee and tea planting, wheat and maize growing, or for mixed stock and arable farming. There is now a large amount of material available based on the experience of some thirty years, from which the A. draws certain conclusions. The A. has summarised the points of view: of: (a) Kenya; (b) the settlers; (c) the natives; (d) the Asiatics and (e) the United Kingdom.

(a) The capital brought in by the settlers has not only met all deficits, but has made practicable a rapid economic development of the Colony. The main wealth of Kenya now consists in the plantations of coffee, sisal, tea and sugarcane, which owe their existence to the enterprise of the settlers. The quality of the native-owned live-stock has been improved by crossings with the European animals brought in by the colonists. The main disadvantage of European settlement arises from the tension due to the fact that Europeans and Africans are living side by side on the same territory; and also Europeans and Asiatics (Indians).

(b) For the settlers themselves, the colonisation has not—with some few exceptions—been profitable from the economic standpoint. Farms and agricultural undertakings, in which more than £ 32,000,000 have in all been invested, are not now worth more than one third or two-fifths of that sum.

A large number of settlers have already left the country, and others have seen that the climate does not suit either themselves, their wives or their children. (The book contains some very interesting observations on the influence of the climate of the highlands on the Europeans who live there for a number of years).

Settlers often find that lands which they have taken up are not worth farming owing to their poor yield.

---

\* Under this heading are included short synopses of books received for review.

(c) For the natives the disadvantages of colonisation have been many. Vast tracts of the most fertile lands which they occupied before 1902 have been expropriated, and in addition lands have been alienated to Europeans which would have been required by the natives as their numbers increased. As they can be satisfied with a low yield, natives farm poor lands which the Europeans are obliged to leave uncleared.

A new class of natives has come into existence «squatters» or seasonal workers, without land of their own.

Very heavy taxation, sometimes as high as 50 per cent. of their incomes, are imposed on the natives so as to provide for the requirements of the European population. They are moreover forbidden to grow certain crops which might ensure them a higher level of living.

(d) The political and economic influence of the Indians would undoubtedly be much greater, if the settlers had not done everything to keep them in an inferior position. In consequence of the decision to encourage the establishment of Europeans, a scheme favouring Indian settlement was abandoned.

(e) It is possible now for about 15,000 persons of British origin to live on the incomes they draw from Kenya; these include not only settlers, but also Government officials, traders, manufacturers, whose numbers have decidedly increased, in consequence of the policy of white settlement.

According to certain figures quoted by the A., it would appear that from the financial point of view, the United Kingdom has done well out of Kenya. Kenya loans constitute fairly advantageous investments for British investors. Investments in European agriculture were profitable during periods of prosperity such as that of 1924-29, but between 1921 and 1923 or between 1930 and 1934 heavy losses have had to be met.

The trade between the United Kingdom and Kenya is of small importance as compared with the total trade of the United Kingdom. The only Kenya product which has acquired some importance is coffee; in 1935, 46 per cent. of the coffee imported into the United Kingdom came from Kenya.

From the economic standpoint there is no advantage for Great Britain in buying from Kenya rather than from other countries, since prices of the principal Kenya products are fixed on the basis of prices of the same products in the large producing countries.

*Offices Météorologiques du Monde avec leurs Directeurs et Etats-Major, leur attribution de service et leurs publications.* Utrecht 1938. Imprimerie Brookhoff N. V. (Secrétariat de l'Organisation Météorologique Internationale, N° 2).

[International scientific collaboration is often seriously hampered by ignorance or inadequate knowledge about existing technical institutions, which prevents mutual contact of persons whose interests lie in the same direction. Publications remedying this situation are therefore of great value, this is eminently true of the directory which has just been published by the International Meteorological Organization and which contains—on movable slips—authentic and recent information in respect of the official

meteorological services as well as of the independent institutions of all the countries of the world. The name, address, scientific staff and functions of each administration and institution are shown; the titles of their periodical publications are added. The directory will be kept up to date by means of supplementary slips. This international register of meteorological services is of direct interest to farmers, as the majority of the offices deal with agricultural meteorology].

## AGRICULTURAL SCIENCE AND PRACTICE

---

### CANDELILLA: A TECHNICAL AND ECONOMIC STUDY

In view of their many industrial uses, the cultivation of vegetable waxes has always been a matter of importance. Carnauba wax is well-known as a valuable product of Brazil. Candelilla wax, however, is not so well known and the International Institute of Agriculture has pleasure in publishing an interesting technical and economic study on the subject submitted by Señor Miguel GARCIA CRUZ.

Señor CRUZ, in his study, emphasises the importance of this *Euphorbia* in the exploitation of the arid, semi-desert regions of Mexico. He devotes several pages to the botanical description of the plant and its geographical habitat and suggests methods of intensifying production. He discusses at length the possibility of improving the methods in use for extracting the wax. After describing the chief types of wax which compete with Candelilla wax, Señor Cruz proceeds to discuss the economic and commercial aspects of this product and concludes with the statement that by improving the process of extraction and eliminating speculation it ought to be possible to create a regular market for Candelilla wax, which should be able to compete with other vegetable waxes without difficulty.

The following pages contain a very comprehensive survey of a product of which but little is known and the Institute takes this opportunity of thanking the author for submitting a treatise, which will surely be of interest to the readers of this Review.

### CHAPTER I. — PRODUCTION

#### (a) BOTANICAL CHARACTERISTICS.

The Candelilla belongs to the family of Euphorbiaceae and is known by the scientific name of *Euphorbia cerifera* Alc. Its characteristics are as follows: a perennial latex-yielding plant, with branching, membranous stems, slightly flexuose, cylindrical in form with constrictions; the stems are glabrous and of a glaucous green colour. The plant grows to a height of between 30 centimetres and 1.30 metres, the average diameter of the stems being 5 millimetres.

The leaves are isolated and distinct; they are so small that it is difficult to distinguish them on the young shoots; they soon drop off when the stem becomes old, giving the plant the appearance of having been stripped. The leaves on the young shoots are brownish-red in colour but, as a result of a growth of small white hairs, they take on an ashen tinge on the adult stems.

Groups of delicate lanceolate leaves grow on the extreme tips of the branches. The axillary inflorescences consist of uniparous cymes with very small caducous corollae which are villose and coloured; not all the cymes are complete. There are male and female flowers. The fruit is small and stalked. The whitish colour of the stems is due to the large quantity of wax contained in the outer covering.

On examination, the plant shows a thin film of wax covering the stems and sometimes even forming tiny rods like hairs. The wax is found mostly

on the surface of the stems and falls away if the plant is roughly handled, particularly if the plant is dry. Wax is also found in the outer cells of the plant and exudes from special pores. This explains why a higher yield of wax is obtained in laboratories where the plants are treated with a neutral solvent than in industry where solvents are not in use.

#### (b) CHARACTERISTICS OF THE WAX.

The chemical and physical properties of Candelilla wax are as follows:

Density at 15°C . . . . .	0.9320
Index of saponification . . . . .	1.4545 to 1.4646
Saponification figure. . . . .	35.0000 to 36.5000
Iodine index . . . . .	14.4200 to 20.4000
Non-saponifiable substances . . . . .	76.7000
Hydrocarbons . . . . .	45-52-70

Chemical analysis of a wax obtained from the northern region gave the following results:

Moisture. . . . .	1 %
Wax . . . . .	423 %
Resins . . . . .	14 %

The properties of the wax vary slightly in relation to the time of year at which the plant is picked and to the age and origin of the plant.

Generally speaking, winter wax has a higher melting point, greater density and a lower content of volatile acids than summer wax.

The extraction of Candelilla wax with various solvents has been tested both in Mexico and abroad; the most important of these solvents are: turpentine, amyl alcohol, ethyl alcohol, methyl alcohol, ether, sulphuric acid, benzene, chloroform, acetone, petroleum, petrol, petroleum ether and carbon bisulphide.

Comparative tests have been made with certain solvents on 20 grams of Candelilla wax, the results being as follows:

	Wax %	Resin %
Turpentine . . . . .	5.35	24.54
Petrol . . . . .	5 —	24.20
Alcohol . . . . .	4.50	22.85

The great importance of these solvents will be realized and the relative efficiency of the most suitable processes of extraction will be explained when the methods of extraction are discussed.

#### (c) CLIMATE AND SOIL.

In the regions where the Candelilla grows, the climate is so severe that it would not permit of the growth of any other serviceable plant. The limits of the zone where this plant grows coincide with the arid and semi-arid regions

of Mexico. The climate is that of a desert, with heat like that of the steppes or else of the Sahara.

Extremes of temperatures are found in the steppe type of climate. Data collected at the meteorological stations in these regions show the following main climatic characteristics:

Station	Average monthly temperature in °C		Average annual rainfall in cm.
	Minimum	Maximum	
Cuatro Ciénegas . . . . .	13.0	38.60	162
Sierra Mojada . . . . .	13.4	28.90	331
Monclova . . . . .	12.0	28.70	353
Sabinas . . . . .	10.0	35.60	553

It should be observed that the figures given above are not absolutely applicable to the Candelilla producing regions, as the meteorological stations are situated in desert oases or in places where natural conditions are more favourable and permit of the growth of enough vegetation to encourage the establishment of small rural communities. Generally speaking, the Candelilla is found where the annual rainfall is considerably lower than 100 millimetres and consequently it may be said that the plant grows under the minimum natural conditions required for growth particularly in so far as moisture is concerned. The exploitation of the Candelilla is therefore very important for the agricultural future of the large tracts of desert land in the north of the country.

The types of soil on which this plant grows vary considerably. The Candelilla is mostly found on sandy soil which is generally poor in humus. Chalky soil rich in potash would be the most suitable for the growth of the plant but would have the disadvantage of producing too luxuriant foliage yielding very little wax.

#### (d) PROPAGATION OF THE PLANT.

The propagation of the plant is very difficult, the seeds being rare and hard to gather. Nevertheless, in the natural state a large number of plants are produced by seed germination.

Many different types of plant propagated at random in the natural state can be made to multiply most satisfactorily with human aid. But certain difficulties arise in the case of the Candelilla in spite of the plant's great vitality; first, economic difficulty of the high cost of collecting the seed, and secondly, the technical difficulty of sowing seed in soil which is so arid that man refuses to settle there. Moreover, the artificial propagation by seed of the Candelilla does not effect any saving worthy of mention.

With enlightened treatment by cultivators, taking due count of the many requirements of the plant, it will undoubtedly be possible to obtain abundant

propagation by cuttings of different kinds and by taking advantage of the small amount of rain which falls each year.

Till now there has been little inducement to cultivate the Candelilla as there are still vast areas where the plant grows wild and which have not yet been exploited. Nevertheless, the exploitation of the natural reserves is limited by a number of factors which set bounds beyond which it is impossible to advance and which oblige farmers to return to the areas already exploited. If there is a sufficiently large demand for the wax, the best land will be exhausted and will have to be left for a certain period in order to recover.

Undoubtedly the exhaustion of plants in the wild state will make it necessary to have recourse to artificial propagation, and the exploitation of the Candelilla will become generative instead of purely extractive when the natural reserves have become insufficient to meet market requirements.

(c) FACTORS AFFECTING THE GROWTH OF THE PLANT.

The climatic conditions of the desert area producing the Candelilla are certainly not the most suitable for the growth of the plant; for in regions where rain is heavier and the terrain more favourable, the Candelilla produces a more abundant growth, but there is a decrease in the wax content. It may therefore be stated that the industrial value of the Candelilla is in inverse proportion to the development of the plant, *i. e.*, to the fertility of the area where the plant grows, and there must be an optimum ratio between the two, giving a maximum yield. This does not imply that the present areas where the Candelilla grows wild are the best. The conditions under which the plant gives a maximum industrial yield could easily be verified by establishing experiment stations.

There are a number of other factors which have a considerable influence on the growth of the plant and are connected with the methods of exploitation employed. Among the favourable factors are winter rains which enable a partial regeneration of a large number of plants in a dying condition.

The plant bears fruit from May to July and seed germination is favoured at that time by the first summer rains. Lack of rain and severe winters, at the time when exploitation is most intense, are unfavourable for the regeneration of the plants and contribute to their destruction. Although the Candelilla is of no use as fodder for cattle, the plants are often damaged and trampled by the livestock frequenting ponds near the exploited fields.

Goats enjoy browsing on the young shoots in the springtime and this is one of the principal causes of destruction apart from the action of man.

Candelilla exploitation and the rearing of livestock have the same requirements as regards water, but otherwise the two industries are injurious to each other and there is a tendency to separate these two forms of agriculture.

There are several insects which lay their eggs on the young stems of the plants, the larvae destroying the tips of the branches; nodules like capsules are thus formed on the tips, and all branches attacked by these insects either die or fail to send out any young shoots until the following spring.

At the historic farm of Guadalupe in the commune of Ramos Arizpe, Coahuila, it was observed that all the Candelilla fields were infested. The unexploited fields were more seriously affected than the others, exploitation contributing indirectly to the destruction of the pests as the larvae are killed in the process of boiling the plants to extract the wax. When exploitation is most intense, however, the disease remains latent and its destruction by the above method is practically nil, or in other words exploitation merely contributes to the reduction of the disease at the least suitable period for extraction, *i. e.*, when the plant puts out its first shoots.

At the present time it is impossible to organise a campaign against this pest, since the exact extent of the area attacked is as yet unknown. It is therefore of primary importance to carry out studies from every standpoint in the hope of discovering an effective means of combating the pest.

The present method of exploitation is unsatisfactory and is probably the cause of the destruction of the plant since, as will be seen later, the exploited fields can only recover to a certain extent.

#### (f) GEOGRAPHICAL AREAS.

The Candelilla grows wild in various States of Mexico but is utilised industrially only in the following States: Coahuila, Nuevo León, Chihuahua, Durango and Zacatecas.

Candelilla reserves are to be found in many other States of the Republic, but for various reasons it has not been possible to exploit them, partly because of the small wax content of the plants and also because of the very unsatisfactory methods of extraction adopted. The following are the chief areas where the Candelilla grows:

Cohuila	Jalisco
Nuevo León	Sonora
Chihuahua	Baja California
Durango	Puebla
Zacatecas	Oaxaca
San Luis Potosi	Hidalgo
Tamaulipas	

Candelilla is thus distributed throughout the entire area of the Republic, and sufficient importance has not yet been attached to its exploitation.

Candelilla is exploited only in the five States at the head of the list, while in the others it constitutes a potential source of wealth which can be realised when increasing demand on the market creates favourable economic conditions for the extension of the area exploited. An increase in production can be obtained by various methods, and especially by the exploitation of the plant through the introduction of more satisfactory methods of extraction, by the construction of roads and railways, by the creation of reservoirs, etc.

## (g) AREAS EXPLOITED.

The few statistics available concerning the production of Candelilla wax make it possible to give an idea of the distribution of the exploited areas. These statistics may be summarised as follows:—

TABLE I. — *Production in producing States of Mexico from 1933 to 1936.*

States	1933	1934	1935	1936
Coahuila . . . . .	793,563	231,343	814,323	2,577,631
N. León . . . . .	155,663	64,824	137,863	1,303,470
Durango . . . . .	—	2,110	648	—
Chihuahua . . . . .	—	—	—	152,115
Zacatecas . . . . .	—	1,406	—	67,226
Total production . . .	949,226	299,683	952,834	4,100,000

It was found impossible to obtain exact figures concerning the total *value* of Mexican production during 1935 and 1936. An indication of the amount may, however, be obtained from the fact that the value of production in the four principal States amounted to 590,000 pesos in 1933 and to 190,000 pesos in 1934.

The exploited areas vary from year to year. Candelilla was exploited in the State of Chihuahua as long ago as the beginning of the present century but exploitation was interrupted for a long period and only renewed in 1936.

## (h) ESTIMATE OF PRODUCTION IN MEXICO.

A study of the production and export figures for Candelilla wax often shows that exports are greater than the production estimates. Since there are no reserve stocks in the country it is obvious that the figures supplied by the Forestry Department are far below the actual quantities produced. It is therefore impossible to give exact figures.

## (i) CHANGES IN AREAS EXPLOITED.

It has already been shown how the exploited areas vary from year to year as the result of exhaustion of the fields. In 1933, for instance, the two municipalities which produced the greatest quantity of wax were Cuatro Ciènegas and Monclova, but in the following years they are not even mentioned as having produced wax.

Many similar examples of the shifting of exploitation could be given. These changes are caused by the exhaustion or the regeneration of the wild growth, by the labour supply, the state of the roads, the demand for wax, etc. Undoubtedly also the productive capacity of the areas under consideration and labour conditions affect these variations considerably.

When the crop season appears to be good, or when the population has other occupations, the inhabitants prefer other crops or other forms of labour involving less toil and more profit, with the result that the production of Candelilla wax declines. When the crop situation is unfavourable, however, the inhabitants then try to fill the gaps by exploiting the Candelilla with a consequent increase in wax production.

These economic considerations naturally affect the shifting of the areas exploited. Generally speaking, however, it is the exhaustion of the plant which is the principal cause of these changes, making a lapse of three, four or even five years necessary between the periods of exploitation, so that partial recovery of the plants may enable a profitable renewal of exploitation.

#### (g) PROSPECTS OF EXPLOITATION OF NEW AREAS.

In those States where the Candelilla is at present being most intensively exploited, there are still vast areas where the plant grows without being utilised owing to lack of water. Señor Raoul MADERO, in an article dealing with this subject, states that water is one of the essential factors in the exploitation of the Candelilla plant. This plant, he says, may be found in arid regions entirely without water, and where it is often impossible to find water even in the subsoil; in other cases the soil is so permeable and the flow of water so slight that it is impossible to consider the possibility of building reservoirs or dams.

Since water is, as has already been stated, one of the essential elements for exploitation, it is interesting to know at least approximately the quantity required.

Experience has proved that 35 litres of water are required for the production of one kilogram of crude wax; with the addition of the water required by the workers and transport animals, the total amount required becomes 70 litres.

It has already been seen that the exploitation of the Candelilla is carried on in areas supplied with water adjacent to the pastures of stockbreeding farms where reservoir and cisterns have been constructed and where spring water is available.

Almost all the work carried out in connection with farm water supplies is done in order to provide water for livestock and only as a secondary consideration for the exploitation of the Candelilla. This industry has therefore had but slight influence on the construction of noria pumps and cisterns; the wax industry has almost always been subsidiary to other more stable and permanent industries such as the rearing of livestock.

The best quality plants are not as a rule utilised in the exploitation of the Candelilla because, as has already been stated, these plants grow in the least favourable regions where it is difficult to find sufficient water for exploitation.

The cisterns built for the use of stockbreeding farms will, of course, serve indirectly for increasing the exploited areas, but such expansion will not be extended to the best regions because the areas most suited to the Candelilla do not contain pastureland and also because, as has already been said, the optimum conditions for exploiting this plant and for stock raising are not exactly the same.

Each wax factory is situated at a certain distance from reservoirs and extraction can only be carried out in cases where transport of the raw material can be effected at an economical cost. A rise or fall in the price of wax immediately results in an increase or a decrease of the area exploited. If the market demand continues to rise, there is no doubt that the factories will extend their radius of action, but this will always be limited by the cost of transporting the raw material from the point of production. The Candelilla reserves are extensive, however, and are capable of producing much larger quantities than are at present in demand.

#### (A) EXHAUSTION OF THE PLANT.

The production of Candelilla wax presents all the characteristics of an extractive industry; those interested are content to exploit natural stands without attempting artificial propagation of the plants, which are allowed to multiply spontaneously. Although reserves are large enough to satisfy present requirements, this may not always be the case. The extractors of Candelilla wax believe that the plant cannot die out because the general method of exploitation serves as an indirect means of propagation. It is sufficient, however, to recall the biological characteristics of the plant and the method of exploitation in order to realize that exactly the contrary is the case.

The most intensive exploitation takes place during the winter, when labour is most plentiful, other field work being at a standstill, and when wax production is at its best, as the Candelilla loses its water during frosty weather and increases its stock of wax as a natural means of protection. This increased exploitation during the winter months is gradually exhausting the Candelilla fields, a large number of the plants which are torn up at that time ceasing to send out shoots.

When the plant is pulled some of the roots usually remain in the ground but these cannot resist the cold weather. Some very old Candelilla farms which were abandoned when the plants became exhausted are still to be found. This exhaustion does not take place very rapidly and it is possible to obtain three or four cycles of exploitation lasting a total period of 12 to 16 years by allowing the fields a partial rest every three or four years.

#### (B) ECONOMIC ASPECTS OF EXPLOITATION.

In exploiting the Candelilla only the reserves created by nature without the farmer's intervention are utilised. This is a transitory situation, however, and there is no doubt that if the demand for wax were to increase, working of the Candelilla would gradually be transformed into a real farm industry.

## (iii) INDUSTRIAL USES OF CANDELILLA WAX.

The uses to which Candelilla wax is put depend on its properties which vary with the season of gathering and the age of the plant. The wax extracted during the winter has a higher melting point than that taken in the spring or summer; its acidity and saponification index are also higher and its colour darker.

Comparison with other types shows that Candelilla wax is harder and less brittle than Carnauba wax; when melted it is more viscous than the latter, while it shows the same points of difference from beeswax. In general appearance it is more like a resin than a wax. It has two outstanding defects militating against its utilisation: the difficulty of blanching and its high content of resin. Mixed with other waxes which raise its melting point, it can be used for the manufacture of candles. It is also utilised in the preparation of bitumens for road-surfacing as its low melting point gives it a hard and brilliant surface and its viscosity prevents evaporation of the turpentine essence and other substances used for obtaining bitumen and fats.

Candelilla wax is used in the manufacture of varnishes because a brilliant surface, constituted by a thin film of protective wax, remains after the solvents have evaporated. It is also mixed with rubber and guttapercha for the manufacture of electric apparatus, insulators, etc.

Mixed with other waxes and fats, it serves as a furniture polish. It is also used on a very small scale for modelling wax figures, flowers, etc., and in the manufacture of waterproofed articles. The Government of the United States used Candelilla wax in large quantities for waterproofing tents during the Great War.

It can also be mixed with Sapote gum (chicle) and other oriental gums for the manufacture of chewing gums; this use is decreasing, however, as jelutong and other gums now replacing chicle do not require to be mixed with Candelilla wax.

Wax matches, explosives, gramophone records, candles, carbon paper, etc., are also manufactured from Candelilla wax, and the product is also used by the Mexican peasants as a finish in the tanning of certain hides. The juice of the plant serves as a purgative and infusions of the leaves give a liquid which is used in the treatment of gonorrhea and syphilis.

TABLE II. — *Characteristics of the various waxes.*

Characteristics	Candelilla Wax	Japanese Wax	Carnauba Wax
Saponification Index . . . . .	106.0	221.30	87.0
Refraction Index . . . . .	45.0	47.0	86.0
Iodine Index . . . . .	5.5	4.5	13.5
Acidity . . . . .	0.03	9.25	0.01
Melting point . . . . .	75.0	51.0	85.0
Density at 15° C. . . . .	0.947	0.977	0.99

## (2) SUBSTITUTES FOR CANDELILLA WAX.

In the following table will be found some comparative figures concerning Candelilla, Japanese and Carnauba waxes.

It is interesting to note the melting points of the principal waxes which compete with Candelilla wax.

	Melting point in °C.
Palm Wax . . . . .	83
Carnauba Wax . . . . .	82
Chinese Wax . . . . .	82
Candelilla Wax . . . . .	75
Beeswax . . . . .	61
Japanese Wax . . . . .	42
Myrica Wax. . . . .	42
Ocuba Wax. . . . .	40

A few remarks concerning the various substitutes may be of some interest.

(1) *Palm Wax*. — This wax, obtained from the *Ceroxylon andicolum*, a species of palm growing in the highest parts of the Cordillera of the Andes, is extracted by grating the bark and boiling the resulting powder. The melting point of this wax, which has almost the same qualities as Carnauba wax, is between 85 and 86° C.

(2) *Carnauba Wax*. — This is extracted from the *Copernicia cerifera* wax palm which is very common in Brazil, Venezuela and Colombia. The method of extraction is simple. After being dried in the sun, the palm leaves are grated and allowed to soak until the wax runs off, when it is set aside to be decanted. The yield is one kilogram of wax per 250 or 300 leaves. The essential components of this wax are myricile palmitate, myricilic ester and palmitic acid. Its high melting point (between 82 and 90° C.), leads to its frequent use for the conversion of fats into more easily melted substances and also for rendering paraffin and ozocerite suitable for use in the manufacture of candles.

This wax is of a slightly greenish colour but when well prepared is yellowish white; it is tasteless, very hard and brittle and easily ground to powder. It is soluble in ether and in boiling alcohol. Mixed with beeswax, it is used in the manufacture of candles. When added to paraffin and stearin it raises the melting point, the addition of about 15 per cent. of wax being sufficient to raise the melting point by 10° C. It is utilized in the manufacture of creams, gums, decorations, gramophone records, etc.

It has been used for some time in the manufacture of a special soap called Carnauba soap. In view of its characteristics, Carnauba wax ought rightly to be considered as a fat, but as it is always looked upon as a wax by the trade, this designation will be retained in this study.

Annual exports of this product from Brazil have increased slightly between 1910 and 1935, having risen from 6,000 to about 7,000 tons. The largest importer is the United States, which takes half the Brazilian output; other large importers are Great Britain, Germany and France. The export figures

show that purchases by importing countries have been perfectly steady for some time, which indicates that the market is firm. Candelilla wax exports, on the other hand, are most irregular, this product being utilized only intermittently.

(3) *Chinese Wax*. — This is produced by the insect *Couis Cerifera* which deposits the wax on the trees where it lives. It is very similar to spermaceti and is a brilliant white, melting at 82° C.

(4) *Beeswax* is very common in Mexico and there is a great future for exports. Its melting point is between 61 and 63° C.

(5) *Japanese Wax* is extracted from *Rhus vernicifera*. The glyceride or fatty substance obtained from the *Rhus sylvestris* (a tree which grows in China and Japan) is also improperly called Japanese wax. *Rhus vernicifera* is also found in Indochina and in India. The fruit contains from 20 to 25 per cent. of fatty substances and from 40 to 65 per cent. pulp. The ordinary wax is a greenish-gray colour with a slightly resinous smell; it is brittle and of a crystalline structure. Under the action of heat the wax becomes brownish and covered with powder, melting between 48 and 50° C. It is soluble in boiling alcohol, the solution coagulating into a granulous and crystalline mass as it cools; though it does not dissolve readily in ether, it is immediately dissolved by water. Its essential components are palmitic acid (13 per cent.) and soluble isobutyric caprylic acid; unlike the other waxes, when heated with bisulphide of potassium it gives off a pungent odour of acrolein.

Its trade names are Kobe Kitagumi and Japanese wax, and it is shipped in bales of 200 kg. It is used for polishing articles made of turned wood, and for the manufacture of candles and soaps. Japanese wax is utilized in Italy for the manufacture of wax matches and also as an imitation of beeswax. It is generally mixed with other waxes.

(6) *Ocuba Wax* is extracted from the stones of the fruit produced by the *Myristica surinamensis*, a tree which grows in the State of Pará, along the Amazon and in French Guiana. It is olivegreen in colour, melts at 40° C., and is suitable for the manufacture of candles.

(7) *Wax from the Myrica cerifera*. — This wax is obtained from the fruit of the *Myrica cerifera* and is known as Luciana or vegetable wax. It is found in the form of a whitish efflorescences covering the fruits of the various species of the *Myrica* genus. The wax is produced by secretory organs and is deposited in a blackish film over the surface of the fruits. These same secretory organs produce a highly perfumed oleoresin which is mixed with the wax. When the fruit is plunged into hot water the wax melts and floats on the surface of the water; the longer it remains there the darker it becomes. It is then purified by melting and poured into specially shaped moulds for the market. Each tree yields an average of 12 to 15 kg. yearly. Owing to the chlorophyll contained in the fruit, the wax is greenish in colour; as it ages it becomes covered with a fine, compact film which gives a whitish or greyish appearance. This wax is harder than beeswax but not so hard as palm or Carnuba wax. When heated it melts at between 42 and 49° C., the liquid wax having a smell similar to that of rosemary.

According to MOOR, this wax consists of palmitin and laurin and should therefore be considered as a fat. In the regions where it is produced it is used as an anti-diuretic and for the same purposes as beeswax. There are extensive *Myrica* plantations in Mexico, especially in Vera-Cruz, Hidalgo, San Luis Potosi, etc. This product is often wasted as it has not been much studied, but it is probable that it might become an important product for export from Mexico in the future.

A general description has been given of the chief uses and properties of vegetable waxes used indiscriminately in the manufacture of various articles. As there is a great variety of these waxes and as they have no individual characteristics leading to their adoption for special purposes, prices do not fluctuate much. A sort of balance is maintained as a rapid rise in the price of a particular wax immediately causes traders to purchase other types of the product.

#### (C) METHODS OF EXTRACTION.

Candelilla wax has been exploited since the beginning of the century and little improvement has been made in the method of extraction since then. This is due to a number of factors which are deserving of analysis. Some manufacturers have erected large factories equipped with modern machinery permitting improved methods of extraction, but even with this equipment the results have been quite unsatisfactory as regards unit yields. The largest factory in the whole region has been installed in the historic farm of Guadalupe, where 2 tons of leaves are treated hourly, but operation is economical only if the raw material can be obtained within a radius of 10 km. When the available candelilla in the surrounding district had been exhausted, the factory was soon running at a loss.

The characteristics of this industrial crop (periodicity, migration etc.), have obliged manufacturers to work with light apparatus which can readily be moved from place to place as the natural reserves become exhausted. Factories are generally planned with a series of basins where the wax is treated by direct heat. These basins are set in hollows in the ground, candelilla refuse being used as fuel. The output of the factories varies according to the size and number of the basins. As a rule, each factory has about ten basins from 50 to 70 cm. in depth and from 1 metre to 1 m. 50 cm. in length, each basin having a capacity of 100 to 200 kg. of Candelilla. The process lasts half an hour. Only those processes of extraction in general use will be described, *i. e.*, extraction by direct heat, extraction by steam and extraction by means of solvents.

(1) *Extraction by direct heat.* — By this method the wax is extracted by boiling the plant. About 8 kg. of sulphuric acid is added to each 1000 kg. of Candelilla; in practice this works out at 1 kg. of acid to 3 kg. of raw wax produced. The whole plant is put into the basins and covered with water (5 litres to about 100 kg. of Candelilla), a fire is lighted under the basin and 200 g. of sulphuric acid are added when the water boils. A black scum immediately

appears on the surface of the liquid and the plant is then kept down in the basins by specially constructed grids fitted to the top of the basins, allowing the scum to float on the surface of the water, which is carefully skimmed and the scum put into special containers. As it cools the scum coagulates into a creamy mass. When a certain amount of this scum has been collected, the first process of refining is commenced by bringing the mass to the boil for a second time, and again adding sulphuric acid. The product is allowed to cool slowly so that it can be easily decanted and separated from foreign matter. The

FIG. 2. — A grid used to keep the Candelilla plants at the bottom of the pit.

of sulphuric acid added. The object of this last operation is to separate the wax from foreign matter and to dehydrate the product to the degree required by trade specifications. When the wax is sufficiently refined it is poured into tin containers or into cement reservoirs for final cooling. When cold, it is broken into little bits and put into jute sacks containing 80 kg. net weight as required by trade regulations.

The refined product is the colour of *café au lait*, while the raw wax is whitish.

(2) *Steam Extraction.* — The second method is not much practised and differs from the one described above only in that heating is effected by means of steam instead of by direct heat. It presents considerable disadvantages as

FIG. 1. — Filling the pit before extraction.

crude wax so obtained still contains 8 to 10 per cent. impurities mainly composed of earth, water and foreign substance. The weight of the wax is usually about 2 per cent. of the weight of the plant before treatment: this is the lowest limit at which exploitation is profitable for small producers. Producers on a large scale can afford to go as low as 1.74 per cent. and still make a profit.

In order to obtain wax for commercial purposes, the raw wax must be boiled again and fresh quantities

FIG. 3. — Skimming the melted wax.

it requires heavy equipment which is difficult to transport and consequently unsuited to the shifting character of the industry.

The plant is put into large lead-lined wooden receptacles traversed by a serpentine for conducting the steam; a metal grill at the top of the receptacles compresses the plant, which is then covered with water, the steam being sent through the serpentine. After a certain time the wax floats on the top of the water forming a blackish scum. The grill is then pressed down on the plant, allowing the scum to float freely, after which it is collected in the same way as in the previous method; the grills are then removed and sulphuric acid is added (about 8 kg. per ton.). The addition of the acid causes a further flow of a large quantity of wax retained in the ligneous parts of the plant. Heating is continued and the contents stirred to facilitate the flow of wax which is then collected as before. When the raw material has been completely exhausted it is set aside for use as fuel.

The scum coagulates into a creamy mass full of impurities, which are eliminated by boiling the wax again. This is effected by placing the crude wax in a clean container with water to which a little common salt has been added and then heating until the wax takes on a slightly yellowish hue. When the contents have cooled the wax comes to the top, leaving all the impurities underneath. It is then removed and submitted to further refinement as in the first method.

(3) *Extraction with solvents.* — If suitable extractors are available this method gives good results. The procedure differs considerably according to the solvent used, although the principle is always the same. One of the best extractors is based on the Soxhlet principle, which need not be described in detail as it is well-known. It will suffice to say that during the process of extraction the temperature is maintained at between 60 and 80° C. for a period of 20 minutes. Meanwhile the steam from the solvents is constantly in contact with the Candelilla and becomes impregnated with the wax. The process is repeated as often as necessary to exhaust the plant's supply of wax; this point has been reached when the solution obtained by cooling the steam emanated by the solvent after it has passed over the Candelillas is absolutely colourless.

The wax is then separated from the resin by means of a centrifugal machine. In this process the precipitation collected should be treated with a little alcohol. The wax remains in the bowl of the machine, while the resin dissolved by the alcohol is thrown out and deposited in an alembic used for the distillation of the residue.

(4) *Extraction by Exudation.* — Patents have been taken out for a process of improving and increasing the yield of Candelilla wax; this method consists principally in causing exudation of the sap through the outer skin, but as the hypothesis upon which it is based is false, the process will not be described.

#### (p) YIELDS.

In order to obtain a slight idea of the relative value of the most usual methods adopted for the purpose of extraction, the wax content of the plant

in the natural state should be known. The results of analyses carried out in various regions are given below:

(a) *Analysis of a dry plant at the Guadalupe farm (Coahuila):*

Moisture . . . . .	52 %
Wax . . . . .	5.20 %

(b) *Analysis of a green plant at Oaxaca:*

Moisture . . . . .	64 %
Wax . . . . .	0.9 %
Resin . . . . .	5.60 %

(b) *Analysis of a dry plant in Baja California:*

Moisture . . . . .	53 %
Wax . . . . .	5.80 %
Resin . . . . .	3.60 %

The data indicate that the wax content of the plant varies from 1 to 6 per cent. and that the maximum resin content does not exceed 5.6 per cent. Certain observations which have not been checked by the author make it possible to state also that the resin content could be as high as 24 per cent.

The yield is affected by various factors and in particular by soil and climate. It has been noted that the excessive moisture and heat of the coastal regions cause a minimum wax yield and a maximum yield of rubber latex. The yield is greatest when the weather is dry as the plant increases its secretion of wax in order to preserve its moisture.

The yield also varies according to whether the plant is gathered in the green state or when dry. Laboratory analyses show an average yield of 5 per cent. for dry plants, although industrial methods barely obtain half this amount when utilizing green plants. In the States of Coahuila, Nuevo León, Durango and Zacatecas, the yields do not vary much, as the plants produced always have the same wax content which is sufficient for industrial exploitation. The same cannot be said for the Southern States, Oaxaca and Puebla, where the wax content of the plant is hardly 1 per cent, and thus insufficient for commercial exploitation.

The industrial methods employed at the present time are not very satisfactory as they only obtain a yield fluctuating between 1.75 to 3 per cent. of raw wax. It is hoped, however, that by using solvents only as a means of extraction, it may be possible to arrive at a yield of 5 per cent. of raw wax. This last method has the further advantage of making it possible to utilise the residue as a by-product of Candelilla exploitation.

(to be continued)

MIGUEL GARCIA CRUZ

## THE DAIRY HERD IMPROVEMENT ASSOCIATIONS IN THE UNITED STATES

As has already been described in the volume published by the Institute in 1935 on "Dairy Cow Testing throughout the world" (1), there are two very distinct schemes of Dairy Herd Improvement operating in the United States and conducting the testing of dairy cows for the purpose of selection. One of these schemes is that conducted by the breed associations which is only concerned with pure-bred animals of the different breeds, while the other deals with commercial dairy stock, regardless of breed, and is conducted by the numerous small Dairy Herd Improvement Associations existing throughout the country.

While the number of cows tested under the Breed Association testing schemes is a comparatively small one (about 10,000), the Dairy Herd Improvement Associations are dealing with about half a million cows. Their influence on the improvement of dairy stock in the United States is therefore very considerable, not only in view of the increasing number of the Associations but also because of the ever improving methods adopted.

The first Dairy Herd Improvement Association in the United States was founded in 1905 in the State of Michigan. The number of these associations rapidly increased up to the year 1930, except for a check during the last years of the Great War. The economic crisis affecting agriculture during the years from 1930 to 1934 caused a retrogression in the development of the Dairy Herd Improvement Associations, but since that year their number has been again rapidly increasing, as shown in table 1.

TABLE 1. — *Number of Dairy Herd Improvement Associations in U. S. A.*

1905 . . . . .	1
1910 . . . . .	40
1915 . . . . .	211
1920 . . . . .	468

1930 . . . . .	1143
1931 . . . . .	1112
1932 . . . . .	1005
1933 . . . . .	881
1934 . . . . .	793
1935 . . . . .	809
1936 . . . . .	876
1937 . . . . .	992

(1) Dairy Cow Testing Throughout the World. International Institute of Agriculture, Rome, 1935, pp. 168.

The 992 associations existing in 1937 comprised a total of 20,758 members with 495,997 cows on test. The great possibilities of development which dairy herd improvement still has in the United States, may be seen from the fact, that even this great number of tested cows represents only 2 per cent. of the cows milked throughout the United States.

The Dairy Herd Improvement Associations are not evenly distributed throughout the country. The majority of them are situated in the north-eastern and middle-western States, where dairy husbandry is more highly developed and more important.

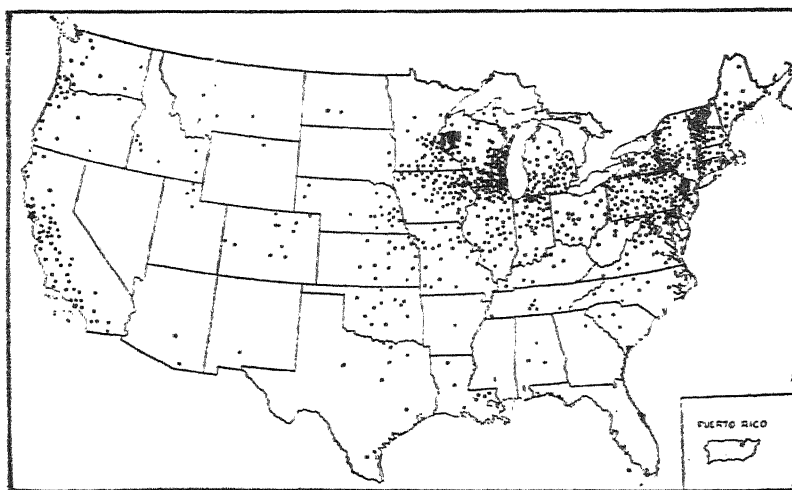

FIG. 1. — Distribution of the 992 Dairy Herd Improvement Associations throughout the U. S. A.  
(Each dot one Association)

### Organisation of the Dairy Herd Improvement Associations.

A Dairy Herd Improvement Association is usually an organisation of about 26 farmers, who cooperatively employ a tester to keep production, feed, income and breeding records of their dairy cows.

The dairy extension specialist and the County agent, who are the State officers charged to assist the local farmers with their advice in all farming and dairying operations also grant their assistance in the case of the creation of new dairy herd improvement associations.

The U. S. Government and the Governments of the single States of the Union help the dairy farmer in many ways in organising and operating their associations. The U. S. Department of Agriculture has established a *uniform constitution* and *uniform regulations* for such Associations and supplies all Associations with the necessary forms and books to be used during the work of the association.

The Government succeeded in this way in making the work of all associations throughout the country almost uniform and in making the results of this

work easily comparable and suitable for the Investigations, which are conducted by the State Colleges of Agriculture and by the Federal Departments, and have the data supplied by the associations work as their basis.

The Dairy Herd Improvement Associations operate under the supervision of the State dairy extension specialist and the local County agent.

In spite of the great help granted by State and Federal authorities, the Associations are and remain free Associations of dairy farmers. As a matter of fact the call for organisation originates usually with the dairyman and the association elects freely its president and secretary.

### The work of each association.

The purpose of a Dairy Herd Improvement Association is to obtain records of production, feed consumption and income for each individual cow in the herd, to be used as a basis for herd improvement. This information enables the herd owner to feed efficiently his cows, to eliminate unprofitable cows from the herd and to keep the calves from the best cows.

But the data supplied by the work of the Dairy Herd Improvement Associations are also largely used for the purpose of improving the dairy cattle stock in the country in general. One of the means in this connection is the proving of dairy sires, effected on the basis of the results obtained by the Associations. This work is carried on by the Federal Department of Agriculture, which records the data of all the cows tested and keeps records as to the progeny and ancestors of these animals, so as to be in a position always to show whether an animal had a favorable or an unfavorable influence on the production of its progeny, i. e. whether an animal is genetically valuable or not.

The objective is to produce by means of the Dairy Herd Improvement Associations improved breeding stock, which will be capable of raising the general production level of the 25,000,000 dairy cows existing in the United States.

### Methods adopted.

The tester employed by the Association visits the farm of every member one day each month. Only in a few instances is a bi-monthly test employed. In this case the interval between the visits of the tester is about 2 months.

During his visit the tester verifies and registers the production of milk and butterfat, the percentage of fat in the milk, the price received for the products, the value of the product, the kinds, amount and cost of roughage and grain fed, the cost of pasture, the total cost of feed, the income of the farmer over the cost of feed and the cost of production per unit of the product obtained. The records made by the tester are thus very complete and give the farmer a picture of the economic value of each single cow, as well as of his entire herd.

In addition to this the tester discusses with the member the merits of the individual cows and offers suggestions on changes of feed and management.

The data obtained by the tester's work are recorded by him first in the *Barn Book*. The tester will enter in this barn book all cows of the herd, whether dry or in milk, and lists them in the same order on each visit. For each indi-

vidual cow the weights of two milkings are recorded separately and then added to obtain the "total of day's milk production". This total is multiplied by the number of days of the monthly testing period to obtain the figure for "Month's milk".

The butterfat percentage is obtained by the Babcock test and also recorded in the barn book. By multiplying the total milk production for the period by the butterfat percentage, the total butterfat production is obtained and recorded.

In a separate column of the barn book the price of the product as obtained by the farmer is registered. The price recorded for the purpose is the average f. o. b. farm price actually received during the monthly testing period. If the milk is separated on the farm and only the butterfat is marketed, both the value of the butterfat and the value of the skim milk are registered and added in order to obtain the "total value of the product".

In order to estimate the quantity of feed distributed to each cow, the tester verifies the quantity of each kind of feed given daily and during the whole testing period. If a concentrate mixture is fed, the percentage of its total protein is also reported.

The cost of feeds, which are not purchased, is mostly fixed on the basis of uniform prices established for each association by a committee which meets at certain times of the year and estimates the values of home-grown feeds for a definite period. These estimates include pasture and silage. In cases where there is no Committee to fix and estimate these prices, they are determined by the tester in collaboration with the farmer.

After having obtained all these data, the tester registers in the barn book the "value of product above (or below) feed costs" as calculated by him.

If the record for each individual cow is complete the tester calculates also the monthly herd total by adding each individual cow record, and the monthly herd average by dividing the monthly herd total by the total number of cows in the herd on the testing day, including dry cows.

In the *herd record book* the records are tabulated on separate sheets for each cow in the herd. The monthly summaries for each cow are transferred from the barn book in the herd record book and are added at the end of each yearly testing period to obtain the total yearly production of each cow.

In most cases the production records obtained during the monthly test are *centred* in order to obtain records of greater accuracy. This means, that the testing day is considered to be situated in the middle of a testing period.

Besides the barn book and the herd record book a *monthly herd summary* and a *monthly Association summary* are kept by the Associations of many of the States of the Federation.

The records of the individual cows are copied by the tester directly without any changes from the pages of the herd record book on the *Yearly Individual Cow Report Blank* which at the close of the testing year is sent to the State dairy extension specialist who forwards it to the Bureau of Dairy Industry of the U. S. Department of Agriculture, for tabulation and study.

Finally, a *Yearly Association Herd Summary* is used, on which the total herd records are listed for each member of the Association.

### Identification of tested animals and recording production performance.

The Dairy Herd Improvement Associations have adopted a uniform system of *ear-tagging* which is applied to all animals not registered in herdbooks and those which do not already bear some official identification marks. The ear-tags are applied by the tester on his first visit on the farm and the identity of the animal is verified on each successive visit.

The tester, besides recording the production and feeding of each animal, has to report each birth of an animal within the herd, giving the exact date of the birth. The newly born animals of a member's herd are ear-tagged on the first subsequent visit of the tester.

The exact recording of births and the identification of the animal enables the U. S. Department of Agriculture to carry on its studies as to the genetic value of the animals tested. The production of the progeny of each sire can be compared with the production records of their mothers and the *index of the bull* established, <sup>(1)</sup> which tells if a bull has improved the production of a herd or not. Each year bulls are proved in this way by thousands and also *outstanding breed cows* are identified in large numbers. Complete production data are accumulated for analysing the genetic make-up of herds in order to identify the *improved lines of breeding*.

Recently *lists of proved bulls* have been published, giving the genetic value of the individual animals. These lists are extremely useful to the breeders, as they give them the possibility to mate with their cows a bull known as an improver of dairy herds <sup>(2)</sup> <sup>(3)</sup>.

### Results obtained by the Herd Improvement Associations.

The gain in average production per cow is generally very rapid during the first years of an association's work. This progress is mainly due to improved feeding and also to the elimination of unprofitable cows from the herd. It has been calculated from the figures of some typical associations that the butterfat production per cow has improved as follows:

First year . . . . .	237 lb.
Second year. . . . .	255 „
Third year . . . . .	278 „
Fourth year. . . . .	292 „
Fifth year . . . . .	305 „

Thus an increase of 68 lb. of butterfat or about 30 per cent per cow is achieved in five years.

<sup>(1)</sup> See "The Problem of Proving Dairy Bulls". *Monthly Bulletin of Agricultural Science and Practice*, No. 3, March 1937.

<sup>(2)</sup> List of Sires Proved in Dairy Herd Improvement Associations, 1938. U. S. Department of Agriculture, Washington D. C. Miscellaneous Publication No. 315.

<sup>(3)</sup> American Indexes of Sires Proved in D. H. I. A. The American Dairy Cattle Club, Chicago, 1938.

While the average production for all dairy cows milked in the United States was in 1935, 4,169 lb. of milk and 164 lb. of butterfat, the average for more than 150,000 yearly records of Dairy Herd Improvement Association cows on test in 1934-35 shows an average of 7,977 lb. of milk and 322 lb. of butterfat per cow.

One thousand five hundred and fifty three bulls have been proved by comparing the 305-day production records of all the daughters (five or more) of each bull with the same records of the dams of the daughters. Altogether the records of 14,802 daughters were compared with those of their dams. The dams produced on an average 9,712 lb. of milk and the daughters 9,553 lb., the dams averaged 372 lb. of butterfat, the daughters 373 lb. The daughters therefore produced less milk and just equalled their dams in production of butterfat.

These figures show the necessity of proving bulls as to their transmitting ability. The tests enable breeders to discard bulls which do not prove to be good transmitters of production qualities.

The Dairy Herd Improvement Associations are therefore to-day much more than a simple scheme for testing dairy cows ; they help the farmers to build up their dairy herds from the point of view of the genetic make-up of the animals. The work of these Associations combine the advantages of a herdbook with those of the testing activity, and this is done regardless of the breed or the general external appearance of the animal. It is a breeding activity based on the production value and the economic profitability of an animal to its owner.

ST. TAUSSIG.

## AGRICULTURAL SERVICES SUPPLIED BY RAILWAY COMPANIES

*(Concluded).*

### Australia. - Victoria.

The first railway built in Australia was between Port Melbourne and Flinders Street; this line was officially opened September 12 1854 and since then has been working without interruption. In early days the Victoria railways were constructed and worked by private undertakings; many of these companies however found it impossible to meet the necessary expenses. In 1857, an Act was passed empowering the Government to undertake the construction and working of railway lines. The last of the private lines was absorbed by the nationalisation scheme of July 1 1878.

The extension of the railway system itself has been the main object of railway policy in Victoria. Hence lines exist in districts where no profits result from the traffic, and, although such an enterprise may be regarded as in some sense a failure, possibilities of development have accrued none the less to the whole district which could not have been ensured by any other means. An example of this is the Mallee, in the North-west of Victoria, which was formerly a waste and which now, as a result of very fine irrigation installations, is covered

with thriving farms and settlements. The State of Victoria is remarkably well served by railways, no agricultural, grazing or non-mountainous district being more than 12 km. from the permanent way.

#### THE PUBLICITY CARPENTERS BY THE VICTORIAN RAILWAYS TO ASSIST PRIMARY PRODUCTION.

The publicity organisation of the Victorian Government Railways Department is generally regarded as the most comprehensive on any Australian railway system, and it has throughout rendered every possible assistance to many aspects of primary production. What is at least of equal importance, the Refreshment Services Branch of the Department has been the medium through which the publicity in aid of fruitgrowers has been supplemented by the practical support of large purchases of fruit.

This assistance, begun over 15 years ago, to primary production, is the outcome of the realisation by the Department that the interests of the railways and of the primary industries were inter-dependent.

By means of the display and distribution of posters and folders, the use of calico signs and of Neon electric signs, the Department may claim to have inculcated into the minds of the population the health giving properties of fruit. Fruit growers on their side recognise the substantial influence exerted by the Department in their sphere. Special attention has been given to the propaganda for soft, canned and dried fruits.

The Department has printed and displayed in all Victorian Government Railway stations many thousands of highly coloured posters bearing the slogan "Eat more fruit", and depicting one or another phase of the fruit industry. In addition, booklets and pamphlets, containing recipes in which fruit of one kind or another is a principal ingredient, have been issued.

In this publicity, the Railways Department has co-operated with public bodies, such as the State Rivers and Water Supply Commission and the Department of Agriculture, as well as with various fruit growing organisations. The Commission and the Victorian Central Citrus Association have shared with the Railways Department the cost of citrus fruit publicity, and the Victorian Dried Fruits Board has co-operated with the Railways Department in dried fruits propaganda.

The publicity work and sales activities of the Department have been effective in disposing of large surpluses of fruit, as appears from several outstanding examples. As far back as 1924, the Department was instrumental in disposing of a pear glut in Victoria. Again at the beginning of 1926, the Department contributed materially to the success of Melbourne's Peach Week, when 70 tons of Elberta peaches were purchased at railway fruit stalls. In 1928, a glut of peaches was successfully avoided, largely owing to the sale by the railways of some 200 tons of the fruit. Later in 1928, a surplus of canned fruit and another of apples were also absorbed by railway sales.

In Victoria the Railways Department is the largest retail customer of the citrus growers. During 1936-37, the Department purchased fruit to the value

of £22,875 including £9,710 for citrus fruits. One of the largest factors in the success of the Department's campaign for popularising consumption of citrus fruits has been the introduction, in the refreshment rooms, stalls and restaurant cars under its control, of the "Sunkist" fruit juice extractors. There are now 84 of these extractors in use on the various premises, etc., belonging to the Department.

In addition, the dried fruit industry has been materially assisted by the large consumption of these fruits by the Railway Bakery which has specialised in the baking of raisin bread. The Department has in fact so far stimulated the general manufacture of this type of bread, that there are now more than 500 bakers undertaking it. At the Railway Bakery alone 9 tons of raisins were used in 1936-37 for making 119,208 loaves. Seven tons of dried fruits were used in the refreshment rooms, and 19,000 packets, amounting to one and a half tons, were sold at railway fruit stalls.

Practical assistance is also rendered to the fruit growing industry by permitting the sale of fruit from trucks attached to goods trains, and by authorising stationmasters to act as selling agents on a commission basis.

It may here be mentioned that the poster "Protective Foods" has been the subject of much favourable comment. It was highly praised at Geneva where a copy was specially displayed during the sittings of the International Committee on Nutrition.

Other primary industries for which the Railways Department has carried out publicity include dairying, wool-growing, beekeeping, potato growing and lamb-raising. Milk drinks have now become a popular beverage at the Railways Drink Stalls and in dining cars, buffet cars and refreshment rooms, the consumption in the course of 1936-37 amounting to 121,000 gallons and nearly 257,000 bottles of milk.

The publicity work for demonstrating the proper methods of handling lambs for export is of special value. Striking posters, accompanied by handbills for distribution among railwaymen and others engaged in the handling of the animals, have been greatly appreciated, and the marked improvement in the condition of export lambs may be largely attributed to this propaganda.

#### VICTORIAN NATIONAL RESOURCES DEVELOPMENT ("RESO") TRAIN.

The initiative in these tours is due to Mr. Harold CLAPP, Chairman of the Victorian Railways Commissioners, who was the first to realise the necessity for leaders of urban and rural industries to become better acquainted with each other and the immense possibilities of the State of Victoria. Thus it was that the Victorian Railways National Resources Developmental Train, a de-luxe train providing the highest standard of accommodation and organisation, was inaugurated.

It was decided to operate this train on tours of one week's duration throughout the primary producing areas of the State. In addition, the co-operation of citizens in various rural areas was successfully obtained in order that those using the train might be shown the farms, the sheep stations, orchards, etc., by the

owners, with whom they would also have the opportunity of discussion. The train utilised for these tours is known as the "RESO" train, the name being an abbreviation of the word "Resources", and 60 passengers can be accommodated. Up to 1938, the number of tours made in Victoria was 28. It is believed that these tours are very definitely;

- (1) Demonstrating the resources and development of the State;
- (2) Fostering settlement;
- (3) Showing the striking results made possible by scientific water conservation and distribution, and sound land settlement;
- (4) Improving the general understanding between town and country interests;
- (5) Enabling farmers in one portion of the State to learn at first hand the methods adopted by farmers in other areas;
- (6) Broadening the general knowledge of Australians in their country's marvellous possibilities and helping to develop an enthusiastic national pride and spirit; and
- (7) Demonstrating the working of the State's greatest industrial asset, *viz.*, the Victorian Railways.

In addition to the 28 tours in Victoria, 14 tours have been conducted to other States, including one to New Zealand in 1938.

#### COMPOSITION OF THE "RESO" TRAIN.

The "Reso" train consists of a parlour observation car, three sleeping cars, dining car, office car, staff car and guard's van. The observation car is equipped with wireless, and refreshments, tobacco, cigars, etc. can be obtained. This car is also provided with special maps and diagrams, which have direct relation to the country traversed, showing closer settlement areas, irrigation, afforestation, etc. Each sleeping car can accommodate 20 persons, and the dining car will seat 48 people. The office car contains typewriters and mimeograph duplicator; this car is also fitted with three hot and cold shower baths. The staff car also has three hot and cold showers, and sleeping accommodation for the officials. The guard's van includes an isolated portion used as a store, and the remainder is equipped with temporary two-tier bunks for the conductors, waiters, cooks, etc. The total length of the train including the engine, is 22 feet, and the weight is 422 tons.

The "Reso" passengers live on the train, eating and sleeping and receiving all the attention which would be obtained at a first class hotel. They enjoy special telegraph facilities and a special postal service. The Melbourne daily papers are supplied to the train while on tour.

Arrangements are made through the local municipal authorities or other public bodies for the party to inspect representative farms, factories, business establishments and any large Governmental undertakings. Usually half a day at each place is sufficient, but sometimes a full day is required. The local residents place at the disposal of the party a sufficient number of motor cars, for conveying them around the different districts. In the evening the local popul-

ation organise a gathering at which members of the " Reso " party are enabled to meet representative residents and to discuss with them any features of the afternoon's inspection. Introductions are facilitated by badges indicating name and business of the wearer in each case.

The Betterment and Publicity Board controls the organisation on behalf of the Victorian Railways Commissioners; a member of the Board usually accompanies the tour as Officer-in-Charge. A shorthand writer and typist who travels on the train is at the disposal of passengers for the performance of any clerical work required. If, as usually happens, the train passes through water conservation and distribution areas, forest regions, closer settlement districts, officers representing the appropriate public departments make the tour to give full information to the passengers.

The trip lasts approximately a week—Monday to Saturday afternoon. As a rule the departure from Melbourne is immediately after midnight on Sunday. The fare is calculated from Melbourne, but special facilities are given to country dwellers to enable them to join the train.

Endeavour is made to secure representation of primary, manufacturing, banking and other industries, as well as of trade in general. Town and country interests are alike represented. The Commissioners themselves determine on the composition of the party, and reserve the right to reflect any application. Each passenger receives a booklet containing full information on the resources of the State, and with his ticket a folder containing useful hints for the journey and an outline of the facilities available on the train. Each morning the " Reso " Daily Bulletin is circulated; this is the train newspaper and contains information as to each of the districts to be visited.

Many expressions of high appreciation have been received from those who have taken part in the tours; among these several representative overseas visitors have expressed their satisfaction and spoken of the great advantage derived from the contacts made in the farming areas of the State of Victoria.

#### THE " BETTER FARMING " TRAIN, AN AGRICULTURAL COLLEGE ON WHEELS.

Appreciating the scope which existed in Victoria for increasing production by impressing on the farmers at first hand the advantages of scientific farming, the Department of Agriculture and the Victorian Railways Commissioners decided to co-operate in the organisation of a " Better Farming " Train. This train commenced running in October, 1924, and is now well known and highly appreciated by farmers throughout the State.

COMPOSITION OF TRAIN. — The train made up of 18 cars, is 817 feet long. It is really an agricultural college on wheels, and it has traversed practically the whole of the State (in some cases it has made a second visit), stopping at suitable centres for a day to enable lectures and demonstrations to be given. Up to June, 1938, the train made 38 tours, in which it has visited 379 centres, and the demonstrations at these places have been attended by approximately 244,500 people, mostly farmers and their wives and families. The maximum attendance at any one place was 5,000.

Up to 1930 the train made two or three tours each year, but with the advent of generally depressed business conditions—which ensued during the next four or five years—the number of tours was restricted for financial reasons. Usually the train runs in the spring and autumn when primary producers are not so fully occupied with their work. The make-up of the train is as follows:

(1) Staff car with sleeping accommodation for portion of the company, kitchen and shower.

(2) Sleeping-car for Lady Demonstrators, with sitting-room, and provided with hot shower-bath and cooking stove.

FIG. 1. — A lecture delivered from the Better Farming Train.

(3), (4), (5) Cattle trucks for the transport of pure-bred dairy cattle of various breeds—Jersey, Ayrshire, Friesian, Red Poll, and Milking Shorthorn. These animals are specially selected from high producing herds.

(6) Truck fitted with 12 pens and provided with a "let down" platform on each side carrying ewes and rams of Australian and British breeds.

(7) Flat truck fitted with pens and canopy, and carrying pure-breed selected pigs.

(8) Flat truck fitted with canopy equipped with models of stock feeding utensils, model gates, silos, concrete posts and other farm utilities. A portion of this truck is occupied by the Publicity Branch of the Department of Agriculture.

(9) Steel louvre truck with fireproof partition, carrying electric light generating plant in one end, and fodder for stock in the other.

(10) Truck containing tiers of wire cages on one side, provided with an automatic watering system and carrying specimens of the different breeds of poultry of both profitable and unsuitable types. On the other side modern poultry farming equipment, such as feeding and watering receptacles, sheds, yards, nests, etc., is set out in model form.

(11) Car containing veterinary exhibits, the main features of which are those indicating the life history and control of the more common internal and external parasites. Other exhibits are arranged to emphasize the necessity for making available mineral licks for sheep and cattle. A portion of the car is devoted to Public Health and Farm Hygiene and contains various model equipment pertinent to the preservation of public health.

(12) Car containing fruit exhibits packed in the correct methods for the home and export markets. Models of graders and packing-sheds, etc., also a collection of destructive parasites. A portion of this car is devoted to honey.

FIG. 2. - Cookery school in the Better Farming Train.

An attractive exhibit of honey derived from different flora is shown, and utensils used in the bee-keeping industry.

(13) Car containing samples of stock feeds and their feeding values. The correct proportions necessary for making up a balanced ration to satisfy the fodder needs of a milking cow are shown. Milk and its products, and the bacteriology of milk are dealt with in this car.

(14) Car containing wool exhibits comprising fleeces of various breeds of sheep to show length, character and style necessary for the correct type of wool from each breed. Portion of this car is devoted to potatoes and the various features which should be associated with successful potato culture. The use of gypsum on stiff clay soils is illustrated.

(15) Car containing boxes of actual sods of growing grasses cut from the field in various parts of the State and arranged to enable comparisons to be made of pastures which have been top-dressed with artificial fertilizers with others which have not. Further exhibits relative to the cultivation of wheat, maize, oats and lucerne are shown in this car.

(16) Car fitted with forms to seat 80 persons and used for lectures and demonstrations on child welfare, home nursing and mothercraft.

(17) Car equipped with cooking range, and show places for the display of needlework, etc., and used for demonstrations in needlecraft and cookery.

(18) Brake van fitted with bunks for the accommodation of the train crew and attendants.

Painted an orange yellow, the train is a striking object on the landscape as it passes through the country. The make-up of the train is altered somewhat in accordance with the farming activities carried on in the districts through which the train runs. In the wool growing districts, for example, a fine collection of sheep and a wool expert are carried, and special provision is made to meet the needs of the wheat and fruit growing districts.

**STAFF ACCOMPANYING TRAIN.** — The train is accompanied by a specially expert staff from the Department of Agriculture, led by the Superintendent of Agriculture. It includes citriculturist, dairy inspector, potato expert, tobacco expert, veterinary officer, sheep and wool expert, entomologist, dairy supervisor, live stock specialist, poultry expert, bee expert and a number of other field officers and assistants in various branches of the farming industry.

There are also experts in needlework and cookery, sent by the Education Department. The Public Health Department sends the District Health Officer in charge of the Public Health Car and a trained nurse to give instruction in mothercraft and the care of children. The Railways Department is represented by a member of the Betterment and Publicity Board, who also attends to the publicity and general organization before the tours are undertaken.

**ITINERARY OF TRAIN AND PRELIMINARY PUBLICITY.** — The itinerary is framed, generally speaking, with a view to holding demonstrations at distances of about 20 miles, and it frequently happens that farmers have been so impressed with the value of the information to be gained from the lectures and exhibits that they journey on following days to the other stopping places, so as to take full advantage of the unique opportunity thus afforded. Representatives of the Agricultural and Railways Departments visit each centre in advance and secure the co-operation of municipal councils, agricultural societies of all kinds, and the leading citizens generally. Posters for exhibition locally and handbills for distribution through every available channel are then sent to the various districts. In addition, invaluable publicity is obtained through local newspapers.

**STOCK ON TRAIN.** — The live stock on the train is for the most part loaned by private breeders and the dairy cattle carried are magnificent specimens of Friesian, Ayrshire, Jersey, Red Poll, and milking Shorthorn breeds (a bull and cow of each). The stock demonstration is a feature of the tours. The splendid animals are paraded and lectures delivered on the wise selection of dairy stock, the necessity for careful breeding and the application of proper herd-testing practices. The elimination of the scrub bull and his replacement by a well-bred and prepotent animal of tested milking strain on the farm is stressed as an important factor in raising the standard of the dairy herd and increasing the butter fat content of the milk yield. A grade cow of good conformation, but

poor production, is also carried to impress upon dairymen the futility of judging by appearance. The farmers are greatly interested in these lectures and at their conclusion the keen questions indicate their desire to learn all that the opportunity permits.

The same applies to the pig demonstration, where Berkshires, Middle and Large Yorkshire breeds are on exhibition. Pig-raising is commanding increasing attention in Victoria and the experts on the train have a busy time answering inquiries on breeding and feeding.

The poultry truck is interesting to many besides the farmer. The birds carried are fine specimens of the leading breeds, and some poor types are also carried for purposes of comparison. The lantern lectures delivered nightly by the expert in this section are always crowded by eager listeners.

The interest shown in the sections alluded to is maintained throughout the train. The breeding and feeding of pigs, diseases of stock, packing and grading of fruit, hygienic methods in dairying, care of the milk from the time it is drawn from the cow until it is finally taken into consumption, all receive the attention their importance demands, and the officers in charge of these departments are gratified at the appreciation expressed by the thousands who seek their advice while the train is on tour.

**WHEAT CULTIVATION.** — The cereal car excites the keenest interest in the wheat-growing areas. Here is vividly demonstrated the great gain to the farmer by adoption of proved methods of fallowing, manuring, seed pickling, proper rotation of crops, by selection of seed, the application of gypsum to stiff clay soil and the methods by which diseases may be guarded against or minimised.

A large tent capable of accommodating 300 people is carried. This is erected near the train and in it the "Better Farming" lectures are given. On the tours throughout the wheat belt, the talks on wheat-growing were attended by an average of 200 farmers daily. At the conclusion of the lectures questions were invited on every aspect of wheat growing and the meetings developed into a series of agricultural conferences for the discussion of problems.

**VALUE OF THE TRAIN TO THE STATE.** — In assessing the value of the tours of the "Better Farming" Train to the primary production of the State, it must be borne in mind that in some branches of its activities it is extremely difficult to estimate in monetary terms the benefits which have accrued. For instance, many wheat growers have volunteered the information that they have definitely increased their yield per acre by following methods advocated on the train in such practices as fallowing, rotation and manuring, as also by sowing the types of wheat recommended. In addition to the gain to the individual farmers, this increase in production is noted by others, who are not slow to adopt similar methods.

In many branches of farming, definitely beneficial results can be quoted as accruing from the lectures and demonstrations given at various centres.

**DAIRYING INDUSTRY.** — The herd testing movement has been stimulated in a remarkable degree by the visits of the train to dairying centres. At the time the train was organised, there were eight Herd Testing Associations in

Victoria — there are now 107, and 80,500 cows are being regularly tested, the average yield of butterfat last year being 244 lb. per cow. Many of the Associations were formed on the day of the train's visit, or at a subsequent meeting of dairy farmers, at which an officer of the train had been invited to attend.

PASTURE MANAGEMENT AND IMPROVEMENT. — The Victorian soils are deficient in phosphates and the application of superphosphate manures has been found almost invariably to have good results in improving the pastures, not only as regards yield in quantity but also with regard to succulence and nutritive qualities.

Since the inauguration of the train, the value of top dressing with superphosphates and of pasture management has been explained by means of lectures and in addition sods of growing pasture taken from experimental plots in the districts visited have been exhibited in the demonstration cars. Where the advice so given has been adopted, there has been an appreciable increase in the carrying capacity of many farms; on a second visit to the same district, farmers have come to the officers of the train to confirm this. On the latest tours of the train through pastoral and dairying areas, an exhibit has been on view illustrating the advantages of the adoption of a system of intensive rotational grazing calculated greatly to increase the carrying capacity of farms; in many districts farmers have put these methods into practice.

FRUIT. — In the fruit section of the train, a feature has always been made of the correct methods of packing and grading; demonstrations of these have been given at all the important fruit centres throughout the State. The Superintendent of Horticulture is convinced that these demonstrations have led to a definite improvement in methods both by individual growers and by packing sheds.

Important results have been achieved by bud—selection, and on the last tour, some growers took the opportunity of having unprofitable varieties rebudded from improved strains.

PIGS. — The Officers of the Department of Agriculture on the train have from the first tour recommended that more attention should be given to the breeding of pigs for bacon production.

In view of the experience in the great bacon producing countries of the world, it would seem that the best results might be achieved by breeding pure bred Large White Yorks, and crossing these animals with the other, ordinary breeds. Recommendations to this effect have been followed, as is evidenced by the fact that while there were only three studs of this breed when the Better Farming train was first inaugurated, there are now more than 70.

The examples given for these various branches of agriculture might easily be extended to include the horse breeding, sheep and poultry industries, in all of which very definite instances might be quoted of improvement resulting from advice given in the course of the tours.

WOMEN'S SECTION. — In the portion of the train devoted to the interests of the housewife, demonstrations are given in cookery, needlecraft, infant wel-

fare and home nursing. It is unnecessary to emphasise the value of the advice given to mothers and to expectant mothers by the Assistant Director of Infant Welfare, especially in districts where medical advice is difficult to obtain.

GENERAL CONSIDERATIONS. — In addition to the material advantages accruing from the information given, one of the objects is to stimulate the aesthetic and social life in the country and to encourage the amenities of the home.

On one of the cars a number of shrubs and trees suitable for ornamental and shelter purposes are carried; lectures are given by Officers of the Horticultural Branch of the Department of Agriculture on gardens, and advice is given as to the most suitable shrubs and trees for the locality in question.

CONCLUSION. — Not only in farming, but also in official circles, the Better Farming train is considered as one of the finest movements inaugurated in the State.

The collaboration between the Victorian Railways Commissioners and the Department of Agriculture has been fruitful, since it has enabled farmers and their families to acquire modern knowledge the application of which is profitable not only to themselves, but to the State as a whole.

### New Zealand.

In New Zealand all matters pertaining to the development of agriculture are within the province of the Department of Agriculture, which is one of the Departments of State.

Railway activities in connection with agricultural propaganda are confined to the promotion of farmers' excursion outings by rail (on the lines of those undertaken in Victoria) during the winter months, in order to provide an opportunity for those engaged in the industry to study farming conditions and operations in other parts of the Dominion at a season when the requirements of their calling do not entail the same close attention as is necessary during the remainder of the year.

These tours are organised with the co-operation of the various farmers' organisations and interested public bodies. Those taking part in them receive hospitality from the farmers in the districts visited and this generally results in invitations for reciprocal visits during the following season.

The itineraries of the farmers' excursions include visits to farming areas, agricultural colleges and various industrial establishments throughout the Dominion. Apart from the recreational value of the tours, they afford opportunities for personal contact between people of similar interests and for insight into the various methods followed in the farming industry in different parts of the Dominion.

The Department of Agriculture has also shown an interest in the tours, members of the different divisions of that Department sometimes taking part in them and giving instructive lectures during the journey. The subjects treated include animal diseases, fertilizers and their suitability to the different classes of soils, and kindred topics.

### Union of South Africa.

The Union of South Africa has a railway system of 21,700 km. making practicable the transport of some 60,000,000 passengers and of 15,000,000 tons of commodities (1934). The railways are almost entirely under State management. The main line is the «Cape—Kimberley—Pretoria» line, which has a number of branch lines.

FIG. 3. - Cross sections of 4 cars used by the South African Railways and Harbours.

Veterinary research car.  $L = 18.20$  m.  $l = 2.10$  m.  $l' = 2.35$  m.

Livestock car, a and c = fodder b = water.

Pig and fodder car. a = young pigs b = fodder c = boar d = pigs

Household Management Car. a = seats b = tables c = sink d = chair  
e = kitchen g = cupboards h = refrigerator i = ironing board j = office.

### SOUTH AFRICAN RAILWAYS AND HARBOURS.

AGRICULTURAL SERVICE. — The South African Railways Administration has never had a regular agricultural service, and at the present time does not undertake propaganda of any kind among the farmers. It would seem of interest however to give some account of an experiment made on the initiative of the Department of Agriculture and Forestry several years ago, consisting of running a demonstration train on the South African Railways.

**DEMONSTRATION TRAIN.** — The rolling stock making up the train was the property of the South African Railways and Harbours Administration and consisted in 13 cattle trucks and disused dining cars, the interior of which had been converted and arranged as exhibition and lecture rooms. The Department of Agriculture and Forestry contributed to the cost £ 5,000, and the whole of the internal equipment was valued at £ 1,000.

The demonstration train was prepared as and when required by the Department of Agriculture and Forestry, which decided the itinerary, undertook the staffing of the train by officers qualified in the various branches of agriculture,

FIG. 4. — Poultry car.

the organisation of all advance publicity and the issue of all publications. The Railway Administration undertook merely the direction of the train services over the various sections concerned.

The object of the train was to bring modern knowledge to the population of the outlying districts and thereby to improve agricultural practices in the Union of South Africa. There can be little doubt that this demonstration train did much for the development of agriculture in South Africa.

Its success was in part due to the fact that it was run at frequent intervals throughout the year, carrying from 10 to 12 lecturers dealing with the various branches of agriculture. Reasons of economy and other difficulties however prevented the continuance of the service.

**INTERNAL ARRANGEMENT OF THE DEMONSTRATION TRAIN.** — The 13 cars were admirably arranged and entirely suitable for the purpose.

(1) The *Horticultural car* was a transformed cattle truck. Various types of ploughs were shown, a cultivator, rakes and hoes, sprayers, etc. Metal receptacles for gathering fruit, etc., and packing plant were also shown. Maps and diagrams were displayed on the walls. (2) The *sheep car* was also a cattle truck arranged with a central passage way and on each side a large and small

pen in which the sheep were placed, separated by a compartment containing fodder. (3) The *Veterinary research car* was a large dining car about 200 yards long, half of which was sub-divided into four small compartments in each of which there was a display of jars containing parasites infesting animals, diseased organs, poisonous plants, etc. The other half of the car was devoted to veterinary prophylaxis and to methods of research. (4) The *Chemical laboratory car* (a former dining car of the same dimensions as the other) included besides three small rooms, two large tables with all requirements for making chemical analyses. A sink was fitted in one of the tables: on the tables there were also upright panels to which were attached diagrams, plans and explanatory drawings. (5), (6) and (7) *Cotton and Tobacco, Crops, Cattle and Pigs* (see figs. 3) were old cattle trucks 40 by 10 feet, converted for the various purposes. (8) The *Poultry car*, which was a large cattle truck 54 feet long, displayed in one part methods of packing eggs, incubators and egg-testing apparatus, and in the other part live poultry. (9) The *Dairy car* (a former dining car) had seating accommodation for persons attending lectures at which the most modern dairy equipment was shown and explained. (10) The *Botanical car* (dining car) was divided into three compartments of almost equal size, holding charts and diagrams illustrating poisonous plants, plant diseases and the means of control; samples of cereals fodder plants and others took up a large proportion of the car. (11) The *Rural Engineering car* was a former cattle truck. (12) and (13) The *Wool and Household Management car* (see Fig. 3) measured 57 and 60 feet respectively. Everything connected with wool, woollen clothing, as well as all household matters, cooking, ironing, etc., were shown. In connection with household management, a woman demonstrator was on duty to show visitors the most recent improvements.

A. BOUSSINGAULT.

## **MISCELLANEOUS INFORMATION**

AGRICULTURAL BROADCASTING IN FRANCE. — The review "Chambres d'Agriculture" (Series I, no. 3 20 février 1939) contains an interesting summary of the present position of agricultural broadcasting in France and suggests improvements which might be made to meet the wishes of listeners.

An international movement in favour of rural broadcasting has been started by the action of the Permanent Committee of the International Institute of Agriculture in Rome, of the International Confederation of Agriculture (18, rue de Bellechasse, Paris 7<sup>e</sup>) and of the International Centre of Rural Broadcasting; in view of this activity and of the efforts made by a number of countries for systematic development of wireless for the instruction and entertainment of rural listeners, the Permanent Assembly of the Presidents of the Chambers of Agriculture have initiated an enquiry in France into this important means of diffusion of information. The object of this enquiry is to collect the views of the Chambers of Agriculture and of farmers on the present methods of diffusing information and instruction by rural broadcasting, for the purpose of co-ordinating and improving the transmissions.

The general lines of this enquiry were published in No. B 3 of April 10 1938 of the review "Chambres d'Agriculture".

Many agricultural journals, the more important daily papers and periodicals have called the attention of their readers to this enquiry. A large number of answers to the detailed questionnaire accompanying the enquiry have been received by the offices of the Permanent Assembly of the Presidents of the Chambers of Agriculture. These have been analysed carefully so as to enable a general report to be prepared. This report has been forwarded to the Minister of Posts, Telegraph and Telephone Services who, on November 7, 1938, had asked for the opinion of the Permanent Assembly of Presidents of Chambers of Agriculture on the subject of Rural Broadcasting and farming talks. The report summarises the principal complaints of listeners on the agricultural broadcasts and suggests certain rearrangements.

Rural broadcasting may undoubtedly become a leading factor in the improvement of the social conditions of the country dwellers and in their intellectual progress. For this reason, it would appear essential to improve the technical conditions of transmission and reception and to undertake an active propaganda scheme for the adoption of wireless programmes really adapted to the requirements of farmers. These programmes should be so planned as to ensure that wireless will contribute to the organisation of leisure time in the country, raise the status of farming, and finally do its part in the diffusion of farming knowledge and in agricultural education. Listeners showed in their replies that they much prefer regular broadcasts given at fixed hours, and dealing with a range of subjects treated simply and practically.

Longer and more important broadcasts might be given in winter; in summer, when there is much outdoor work to be done, they might be limited to the market prices of farm products, weather reports and forecasts and to advice on topical subjects. The most suitable times are meal-times, especially the supper hour.

If these suggestions are to be effective it is desirable to allow rural listeners to express their views on the Management Councils of the State Broadcasting stations and on the Higher Council where, up to now in spite of the efforts made in this direction by the Permanent Assembly of Presidents of Chambers of Agriculture, they have had practically no representation.

An appendix to the report gives a table of the agricultural broadcasts of the State and private broadcasting stations, and a model time table for the winter and summer months, based on the views of the rural listeners who have replied to the enquiry.

G. R.

THIRD INTERNATIONAL CONGRESS OF AGRICULTURAL ENGINEERING (ROME 20 TO 23 SEPTEMBER 1939). — This Congress, which will be held in Rome from 20 to 23 September 1939, has been called on the initiative of the International Commission of Agricultural Engineering, the headquarters of which are at the State Agricultural Institute, Gembloux (Belgium).

The first International Agricultural Engineering Congress was held at Liège in 1930, and the second at Madrid in 1935.

The programme of the Third International Agricultural Engineering Congress was prepared by the International Commission, at the Paris meeting of May 1937; it was ratified later at the 1938 meeting.

The organisation of the third International Congress of Agricultural Engineering has been placed in the hands of the F. I. T. A. (International Federation of Agricultural Experts) under the auspices of the International Commission at Gembloux.

The Third Congress will be held at the International Institute of Agriculture.

## PROGRAMME OF THE CONGRESS.

*1st Section.* — Chairman: Mr. DISERENS (Switzerland): I. Surface water drainage. II. Problems relating to irrigation. (Amount of water to be supplied according to soil conditions). III. Integral land reclamation, from the point of view of agricultural engineering (Economic considerations).

*2nd Section.* — Chairman: Mr. ARRUE (Spain): I. Ventilation and hygiene of stables and sheds. II. Planning and distribution of farm buildings. III. Storing of farm products and crops.

*3rd Section.* — Chairman: Mr. COUPAN (France): I. Generation of power by means of gas generators. Vegetal and mineral fuels for gas generators. Adaptation of gas generators to farm vehicles. II. Studies relating to soil mechanics. III. Standardization of machine testing. IV. Standardization of machine parts. V. Agricultural applications of electricity.

*4th Section.* — Chairman: Mr. MICHELI (Italy): I. Farm machinery considered from a social point of view. II. Influence of engines in farm economics. III. Scientific organization of work in agriculture: (a) in research stations; (b) in Institutes and Schools.

For all information relating to the Congress, application should be made to the General Secretariat, Rome, Via Regina Elena 86.

G. R.

The INDIAN CENTRAL JUTE COMMITTEE. — This Committee, the establishment of which was recommended by the Royal Commission on Agriculture (1928), was set up under a Government of India resolution dated May 28th 1938. The Committee consists of agricultural and scientific experts and an equal number of representatives of the Indian Jute industry. The programme of work includes: (1) enquiry into the marketing and transport of jute and its products; (2) agricultural research and supply of improved seed; (3) technological research such as the spinning quality and the correlation, if any, between this and the measureable characteristics of the fibre; (4) a full crop census—both by census and random sampling methods—chiefly with the aim of meeting the urgent need of improving the accuracy of the jute forecasts; (5) collection and distribution of statistical information on the world demand for jute so as to assist Indian growers to decide on the acreage to be planted to jute from year to year; (6) advice to jute growing provinces on acreage, standardisation of quality and grade, legislation regarding standard weights and measures, establishment of regulated markets on an experimental basis, etc.

The Committee will have its own laboratories and has been greatly assisted so far by the Governments of Bengal, Bihar, and Assam in the matter of agricultural research, forecast improvement and district propaganda. It publishes a monthly bulletin.

G. T. K.

## BOOK NOTICES \*

CESCONI Giovanni, *La Cellulosa*, Roma 1939, 250 pp., 100 figs., 4 plates., 20 It. lire.

[This work on cellulose begins with a study of the plant tissues and describes the morphological characters of the celluloses including those of straw, ordinary cane (*Arundo donax*), bamboo, alfa-grass (*Stipa tenacissima*), sorgho stalks, maize stalks, hemp stalks after decortication, genista and tobacco. The methods of manufacture, of wood and straw cellulose in particular, are then described. Several chapters are devoted to the paper industry, to artificial textiles derived from cellulose, viscose products and to the products obtained from cellulose derivatives.,,

The last part of the book deals with economic aspects and discusses the world cellulose problem and the prospects of wooded countries and of those in which timber exploitation has made great inroads. Finally, the question is examined from the Italian standpoint with particular reference to the recent efforts to utilise raw materials produced in Italy and in the Italian colonies. The conclusions are optimistic. "When the raw material problem is solved, the cellulose industry will flourish also in Italy. Transformation of vegetable materials into cellulose will be done almost entirely with home-produced raw materials and by Italian labour.

The work is abundantly illustrated and provides a clear guide for experts interested in industrial cellulose production].

G. R.

GAROGGIO Pier Giovanni, *L'olio d'oliva e la sua industria*. Firenze, 1939 (Edizione de «Il Progresso vinicolo ed oleario»), 527 pp. 45 It. lire.

[This work on olive-oil and the olive-oil industry is mainly written for Italian university students and for all olive-oil producers. The first of its four parts deals with olive-oil extraction. After an historical introduction and a description of the raw material (composition, methods of harvesting and conservation), the author reviews the various industrial operations that make up the normal cycle of work in a modern oil factory. The attention of the reader is directed to the new objectives of the technique of olive-oil production and to the full utilisation of by-products.

The second part deals with olive-oil from the chemical, physical and microbiological points of view. The properties of olive-oil, the physical and chemical constants, analysis and detection of fraud and deterioration during extraction and conservation are studied in detail. Rancidity is described in great detail and more fully than in any other book on olive-oil.

\* The third part (olive-oil and consumption requirements) examines defects of oils and their industrial rectification and describes the nutritional and therapeutic properties of olive-oil and the grading and marketing of oils.

The fourth part contains some information on the chemical products used in oil factories and in associated industries. The bibliography would be more useful if it were supplemented by an alphabetical index.

Professor Garoglio's book is a valuable contribution to the study of a subject of great importance to Mediterranean countries. The writing and the presentation of the book deserve unqualified praise].

G. R.

---

\* Under this heading are included short synopses of books received for review.

SCHWIND R., *Der Einfluss von Grubber, Pflug, Klausing-Pflug und Fräse auf Wachstumbedingungen unserer Kulturpflanzen; ein sechsjähriger Bodenbearbeitungsversuch. Aus dem Institut für Pflanzenbau und Pflanzenzüchtung der Ludwigs-Universität Giessen*, 55 pp. 1938.

[The author presents the results of six years of research on the use of cultivators, ploughs, Klausing ploughs and rotary tillers on deep, heavy alluvial soils. These researches were undertaken to discover the effect on soils of different methods of tillage.

Having regard to all the factors affecting the growth of plants, the researches prove that, on given soils which are normally watered and not deficient in lime, a good ploughing at the right time is the most advantageous and the most efficacious method of cultivation. In the light of his experiments the author rejects the continual use of the cultivator and the rotary tiller, for these implements cannot replace the plough.

The effects of the different cultural methods on the structure, temperature, reaction and nutritive substances of soil are indicated briefly below.

*Soil structure.* — Analysis shows that, after treatment with the rotary tiller, the soil bed has maximum porosity. This quality, however, disappears in winter. Only the upper parts of the soil worked with a rotary tiller retain maximum porosity throughout the year. Ploughing with the ordinary plough or the Klausing plough is more effective in the long run on the deeper beds. Working with the cultivator has been shown to be the least suitable method as regards the soil structure, of the deeper parts of the tilth. Only in special cases, for example, immediately after working or at the time of hoeing, is the degree of porosity higher than that obtained by the three other methods.

*Soil humidity.* — Soil moisture depends on the amount of rainfall and the condition of the crops. Working with the plough, the Klausing plough in particular, allows the greatest quantity of water to arrive at the depths reached by the plant roots in the shortest time. Lands treated with the rotary tiller show the greatest variations in humidity, that is the greatest absorption of water at the time of precipitation and plough and the highest evaporation in times of drought.

*Soil temperature.* — Lands worked with the rotary tiller showed the most favourable conditions of growth in the early months of the year while treatments most suitable for growth were, in descending order, the use of the cultivator, the Klausing the ordinary plough.

*Soil reaction.* — The working of the soil had a considerable influence on the acidity of a heavy soil. Even in the first years, surface ploughing (cultivator and rotary tiller) produced signs of acidification. Working with the plough, however, also brought out at the end of four years at the latest, signs of increasing impoverishment. Hence the need for liming every three or four years. The Klausing plough caused no acidification of the soil during the six years of experiments.

*Nutritive substances.* — Acidity induced by superficial ploughing caused fixation of phosphoric acid whereas deep ploughing with the Klausing plough assisted solution.

*Crops.* — On the whole, on lands given a superficial ploughing (with the cultivator or the rotary tiller) yields decreased during the year. Deep ploughing resulted in a better individual development of plants and, consequently, at least for cereals, reduced the quantity of seed necessary].

### CANDELILLA: A TECHNICAL AND ECONOMIC STUDY

(Concluded)

#### CHAPTER II. — THE ECONOMIC ASPECTS OF CANDELILLA EXPLOITATION

##### (a) FORMS OF EXPLOITATION.

The forms of Candelilla exploitation are noticeably different from those adopted for other agricultural products. The three most common are the following:—

- (1) Crop-sharing.
- (2) Leasing.
- (3) Direct exploitation by the owner.

(1) *Crop-sharing* is one of the most usual methods of exploitation followed in Mexico. It is based essentially on a contract between the owner of the land and the crop-sharer, who receives a percentage of the value of production. This percentage varies from 7 to 12 per cent. and can be established on the basis of either the refined or the raw wax.

Sums varying with the extent and intensity of exploitation are paid to the landowner each month by the crop-sharer who also pays the forest tax and all costs of production.

Crop-sharers are generally traders who sell the wax as an indirect means of increasing the sale of articles of prime necessity. The crop-sharer does not undertake Candelilla extraction himself, but leaves this task to concessionaires who take all responsibility for the work of extraction. The crop-sharer bears the expenses incurred in the purchase of equipment, sulphuric acid, and in some cases, the transport of the plant.

The concessionaire bears the expense of picking, transporting and processing the plant up to the point of obtaining the raw wax. He then sells the product to the crop-sharer at prices varying from 0.35 to 0.55 Mexican pesos per kilogram according to the costs of extraction. Generally speaking, concessionaires are persons without capital, small farmers, etc., and are often chosen from among the labourers on large farms. In order to carry out the terms of their contracts, the concessionnaires employ labourers or combine with their

companions. In the former case, a wage-earner can make from 1.50 to 2 Mexican pesos daily; when several concessionaires work together, they divide the profits which may amount to 3 to 6 pesos per head per day. Such partnerships are rare, however, more than 60 per cent of the output being produced by wage labour.

Candelilla wax factories are usually situated in desert regions, far from trading centres and badly served by communications. All articles of prime necessity consumed by the workers and their families have therefore to be transported to the centre of exploitation. A concessionaire is appointed in each factory to attend to purchases and to protect the crop-sharer's interests; he also attends to the feeding of the workers, supervising the work and purchasing all the raw wax produced in the factory and in the neighbourhood of the camp.

(2) *Leasing*. — This form of exploitation is very similar to crop-sharing, the only difference being that the rent is fixed and independent of production. This form of exploitation is not very general but is characteristic of certain regions in the State of Durango. The lessees pay a monthly rent of 100 to 135 Mexican pesos, thus acquiring the right to exploit an area, theoretically undefined, of the great tracts of land where the Candelilla grows. Under these conditions the farmer can thus extract all the wax which his means and equipment are capable of producing.

Of all the different forms of exploitation, this is the most advantageous for the exploiter since the amount of production does not depend on the rent paid; it has, however, the disadvantage that it requires exploitation on a large scale, a system not always practicable for the small independent producer.

(3) *Direct exploitation by the landowner*. — This form of exploitation is carried on in different ways according to whether it is practised by owners of large or medium-sized properties, small-holders or *ejidos* \*. The first group is unimportant because few landowners of this class are interested in the extraction of Candelilla wax.

A large number of smallholders work in cooperation with the large-scale farmers and receive payment from the latter in the form of machinery and loans for paying their workers. The smallholder may work with the large farmers or not as he pleases but, in any case, he himself supervises his sales, pays his workers or gives them a percentage on production. The smallholder may also act as a selling agent for the large farmers, in which case he is paid by the large scale producers or by the exporters.

The *ejidos* work in the same way as small producers. A purchasing agent is appointed to check all raw wax produced and to make advance payments when necessary. There are several cooperative enterprises of the *ejido* type. Several have, however, been abandoned, and now exist only as intermediaries to facilitate the work of the large producers. In many *ejidos*, forest exploita-

---

\* A group of farmers owning land in common.

tion permits are given by the large landowners to a certain number of cooperative farms as an advance on future purchases of raw wax.

In each cooperative, work is done individually, only the sales being made in common. Each member of the community receives in payment the value of his output less the general expenses and personal or collective advances. In some cases, the more intelligent members of these cooperatives try to take on workers from among their comrades at their own expense in order to secure more intensive exploitation for their personal profit.

Advances in cash or in goods are controlled by the nearest merchant who thus centralises almost all the trade of the *ejidos*.

Production by *ejidos* is very insignificant and scarcely amounts to 3 per cent. of the total output.

#### (b) PROFITS OBTAINED FROM EXPLOITATION.

As we saw above, exploitation costs are borne in unequal parts by the landowners, the crop-sharers or lessees, and the concessionaires. Profits are shared in the same way. The concessionaire receives a cash wage of 5 Mexican pesos daily, and, at the end of the season a share of the profits, amounting to about 8 per cent. The landowner receives only 10 per cent of the output or its equivalent in raw or refined wax. Crop-sharers or lessees undoubtedly stand to make most profit for they receive a cash wage of 15 pesos per day as well as a percentage of the profits, so that they can make almost 90 per cent of the total proceeds.

A profit of 300 to 500 pesos per ton of wax, varying according to the conditions of exploitation, may be expected.

#### (c) REFINING COSTS.

The raw wax produced in the factories is purchased by large trading firms (stockage) and then subjected to a refining process which dehydrates the raw product, eliminating all impurities.

Basins of every size are used in this refining process which is effected either by direct heat or by steam. A refining plant is composed mainly of a basin, a boiler, cement tanks, etc., the process being as follows: the raw wax is broken up into small pieces which are thrown into the basin and then subjected to prolonged boiling until completely dehydrated. To facilitate the refining process, sulphuric acid is again added together with a little common salt. During ebullition the wax is stirred constantly to remove all moisture. When the mass is the colour of *café au lait* evaporation may be considered complete and boiling may be suspended. The wax is then allowed to cool slowly in order to facilitate decanting, the impurities falling to the bottom of the basin and the wax coming to the top. It is then put into the cement tanks where the cooling process continues. After 48 hours the wax has solidified into large slabs.

\* *Tec. 4 Engl.*

The process of refining costs at least 13 *pesos* per ton made up as follows:

Refining . . . . .	2.50 pesos
Workers' wages. . . . .	3 pesos
Acid and sundry ingredients . . . . .	2.50 pesos
Fuel . . . . .	3 pesos
Machinery and tools . . . . .	2 pesos

(d) PACKING COSTS.

The wax is then broken into small pieces and despatched in sacks containing 80 kg. net. The cost of the various operations required for putting the product into sacks and weighing, together with the price of the sacks, etc., is very high, amounting to about 16 *pesos* per ton of wax. Sacks are not the best method of packing as they lead to a loss of about 1 per cent. and are easily torn, causing further loss to traders. A better method would be to grind the wax and pack it in cardboard boxes, for this would keep the product in better condition and eliminate part of the loss incurred through packing in sacks.

(e) GENERAL CHARACTERISTICS OF CANDELILLA EXPLOITATION.

The natural growth of the Candelilla plant takes place during the rainy season (June to September). Exploitation is not carried out regularly throughout the year, but varies in intensity, being at its height during the winter months. Little wax is extracted during the rainy season.

The wax, as we have seen, is a secretion produced by the plant as a protection against evaporation; hence the reserves, and consequently the yield, increase in winter. Workers, too, are generally unemployed in winter and wax extraction makes it possible to provide work during a slack period.

There are three factors limiting the future exploitation of the Candelilla plant:

1. Lack of water
2. Exhanstion of the plant
3. Disorganised production.

Extraction is concentrated in the vicinity of water. Livestock rearing and Candelilla exploitation are therefore dependent on the same fundamental natural element: i.e. water. Hence, the two activities are complementary to each other. Nevertheless, as things stand at present, the plant being excessively exploited and the livestock aggravating the destruction begun by the farmer, Candelilla is becoming daily less important as an extractive industry. Since water is one of the factors restricting exploitation, it would be interesting to make an exact estimate of the Candelilla available for exploitation, i.e. situated in the vicinity of water and means of communications.

The economic future of the industry has certain favourable aspects, provided the plant is cultivated and farmers are advised to make tests to determine the possibility of reproduction by means of stem or root suckers.

In regard to the second point (exhaustion of the plant), the poor yield obtained from extraction (50 per cent. of the wax content of the plant), involves a high rate of exhaustion, as it takes 50 tons of raw material to produce one ton of wax. This high consumption will rapidly exhaust the easily exploitable natural growth and, if a rise in price does not compensate the increase in costs resulting from extension of the exploited areas, production will become an extremely hazardous undertaking. It is therefore absolutely essential to adopt improved methods of extraction. Candelilla exploitation consequently passes through periods of crisis and overproduction on the local markets due to speculation and competition from other similar types of wax whose production is better organised and not liable to speculation. It has been observed that many foreign consumers using Candelilla wax in the manufacture of various articles have been compelled to turn to other, similar products owing to the irregularity of the supply. A special organisation is thus needed in Mexico to control production and trade. Such an organisation might be set up on the lines of that already existing in Brazil for the control of Carnauba wax output and trade; the satisfactory results obtained by the Brazilian association can be seen in the favour with which this product is received on the market.

Candelilla wax is not appreciated as highly as Carnauba owing to its high resin content. Its price, however, is lower than its quality merits, Carnauba wax being quoted at three or four times the price of Candelilla. This enormous difference is due to the lack of organisation of production and marketing, rather than to any real difference in quality. Properly presented, Candelilla wax could compare satisfactorily with any other similar product.

Certain foreign consumers have complained of the irregularity of supplies, of a lack of standardisation and of impurities in the product, all circumstances which, as has been said above, oblige many manufacturers to use substitutes for Candelilla. Dealers and merchants are largely responsible for the irregularity of supply many of them exercising a real monopoly over very wide areas. Another reason is that crop-sharers or lessees exploit the plant merely with a view to making quick profits. Candelilla exploiters do not engage in the industry continuously, but consider it merely as a source of immediate profit, never as a permanent and prosperous industry.

### CHAPTER III. — TRADE

#### (a) SUPPLY.

Candelilla wax factories are scattered and are generally found near inhabited centres. There are two methods of assembling supplies, one from large-scale and the other from small-scale production.

*Small-scale independent production.* — Small-scale producers encounter many difficulties in selling their product, as they do not command sufficient capital to refine the wax, despatch it in sacks, etc., and they are obliged to

have recourse to trading firms established in the centres nearest the point of production in order to obtain advances or else to sell their product at poor prices.

The serious disadvantages of this situation are increased by the disorganised state of the Mexican market, even fairly large producers having no connections with foreign importers and thus finding themselves obliged to sell their product to intermediaries in Mexico, which complicates trading and reduces the price paid to the producer.

Production was controlled for a long time by the village shops which found in the purchase of raw wax an easy and sure means of selling their own goods under highly favourable conditions. A large or small shop with wax as its principal source of trade is to be found in nearly every production area. Advances in money or in kind constitute one of the surest methods of effecting these operations. Although in most cases local purchasers are merely commission or sales agents for larger firms or for the big export houses, occasionally they have their own customers abroad and act as exporters on a small-scale.

*Large-scale production.* — Large-scale production is practised by firms specialised in dealing in Candelilla wax. Sometimes these firms extend their control of production to sales on foreign markets but as such cases are not at all frequent, local purchasing by large-scale producers only will be described. It has already been seen that each crop-sharer or lessee producing candelilla wax signs a production contract with the workers living on the exploited area. Under this contract they undertake, among other things, to purchase all the raw wax produced at an agreed price. The factories are supervised by an employee appointed by the exploiter whose chief duty is to purchase all the raw wax produced in the factory and the small quantities which may be produced independently in the neighbourhood. He also refines the product and prepares it for export. When production is carried on on a large-scale, the wax is purchased at the point of production. The cost of concentrating the product in the export centres is borne by the lessee or crop-sharer.

In the case of small-scale independent production, the cost of transporting the wax to the nearest village for sale to the local trader is generally defrayed by the small-scale producer. Large-scale producers often run purchasing agencies in the various localities which collect supplies.

According to available statistics, wax stocks are assembled in the following regions: Cuatro Ciénegas, Monterrey, Reata, San Pedro, Chihuahua and Villa Frontera. As the industry of wax extraction develops, the number of collecting centres tends to increase yearly.

#### (b) THE STATE AND CANDELILLA EXTRACTION.

State intervention has so far been confined to fiscal measures and has been inadequate as regards control of exploitation permits, so that large plantations of Candelilla have had to be exploited without authorisation from the forest authorities. Exploitation permits have also been given in areas where Candelilla

is unknown or where the plant processed has been stolen from other areas. There are no stipulations concerning the quality of the wax nor have any steps been taken to control and regulate production. The forest authorities have not yet made any provision against the danger of exhaustion of the plant following excessive exploitation. It is therefore desirable to work out a rational form of exploitation which would provide a technical basis for protective legislation for this important forest industry.

(c) TAXES.

Production is taxed at the rate of 25 pesos per ton of wax or its equivalent of 0.05 pesos per ton of the plant. This tax is divided between the municipality, the State and the federation (federation 50 per cent., State 30 per cent., municipality, 20 per cent.). An estimate of the sums received by these three departments may easily be made from the production figures. In 1935 the sum totalled almost 24,000 pesos.

Apart from the forest tax, a duty of 12 per cent. is also imposed by the State on railway transport costs, as well as 2.2 per cent. of the shipping freights and 15 per cent. of the value of the cargo. In 1933 the value of Candelilla wax produced in the State of Coahuilla amounted to 18 per cent. of the total value of the forestry production of that State. An idea of the importance of this industry may be obtained from these figures.

(d) FINANCING SUPPLIES.

The method of financing Candelilla wax supplies differs according to the terms of the contract between the trader and the exporter. The product is often bought by the local trader who finds in the purchase of wax the best means of selling his own goods at the highest price; he makes loans to small-scale producers in cash or in kind on the security of future wax deliveries. Independent traders offer their product to exporters, selling it to the highest bidder. In other cases, the traders are buyers or else commission agents for exporters and they purchase the wax for the export house from whom they obtain grants in order to be able to make loans.

The trader may have a fixed commission per ton as payment or he may undertake to purchase at a given top price, in which case he may make good profit out of the difference between the actual purchase price and that obtained from the exporter; the greater the difference between the two prices and the greater his volume of trade, the larger his profit.

Nearly all exporters have agents in the various production areas to deal with the small-scale producer. Two cases may be cited to give an idea of the monthly profits obtained by sales agents. A sales agent in the Cuatro Ciénegas region makes a monthly profit varying between 300 and 500 pesos. An agent in the Bustamante region makes from 300 to 400 pesos monthly. Larger profits are made by traders who make advances in kind. Sales agents

registered in the Candelilla Wax Producers' Credit Union make from 15 to 20 pesos per ton.

Exporters are trading firms possessing resources and credit in nearly all the banking institutions in the region. They give credit to small-scale producers. Small-scale exporters and producers are often obliged to apply to large export firms for credit on the security of future wax deliveries. This system has certain disadvantages because the large export houses always make their sales contract at very low rates notwithstanding the high prices the product may fetch.

All the above information regarding the financial organisation of the Candelilla wax trade relates to conditions which ruled for many years. The situation has now changed owing to the intervention of the Candelilla Wax Producers' Credit Union. The National Foreign Trade Bank has been appointed to administer credits for the Union. On the formation of the National Union of Wax Producers nearly all the small export firms and the large-scale producers applied for membership in this organisation as well as in the Credit Union.

Candelilla wax is a product which is easily stored and it therefore lends itself to speculation. Exporters have controlled trade in their own interests to the serious prejudice of small-scale producers and exporters. Among the methods of speculation employed by large export houses is that of creating a fictitious increase in demand.

Under the new organisation, the National Union of Candelilla Wax Producers, according to the terms of its Statute, forms a group of all the principal export firms and monopolises the Candelilla wax trade to a great extent, thus putting a stop to these forms of speculation.

#### (e) LOCAL EXPORT PRICES.

Local traders sell the wax at prices varying according to conditions. In June 1937 exporters paid prices fluctuating between 0.70 and 0.90 pesos per kg. of refined wax. Small-scale producers can hardly ever sell their product as refined wax because the small traders and exporters usually process the raw wax themselves in order to obtain a standard product. This situation has had a serious effect on the precarious conditions under which small-scale producers work. It may also happen that wax purchased as raw wax is sold direct to the foreign market as the refined product.

#### (f) HOME CONSUMPTION.

In order to form an idea of Mexican wax consumption, a study must be made of annual exports and surpluses for each of the years for which it is desired to ascertain consumption. Between 1920 and 1935 Mexico imported a yearly average of 25 tons of wax and consumed 40 tons of home-produced

wax. It may therefore be estimated that annual consumption in Mexico amounts to 65 tons. Mexican imports of vegetable wax come chiefly from the United States, Germany and Brazil.

(g) CANDELILLA WAX EXPORTS.

From available figures of exports between 1918 and 1936, it appears that this period should be considered in three sections in order to understand the variations due to the decrease in the number of importing countries. These periods are: 1918 to 1923, 1924 to 1930 and 1931 to 1936. During the first period all exports went to the United States. During the second, exports were shipped to eleven countries and were, on the whole, very irregular except in the case of two countries, the United States and Germany, which constituted the principal markets. During the third period, most of the imports went to six countries, the share of each of these six importing countries in 1936 being as follows:

United States . . . . .	69.85 %
Germany. . . . .	14.20 %
France. . . . .	8.00 %
Great Britain . . . . .	3.50 %
Netherlands . . . . .	2.12 %
Belgium . . . . .	1.20 %

The United States have been a permanent market for Mexican wax ever since 1900; Germany has been a purchaser since 1927, France since 1929 and Great Britain, the Netherlands and Belgium since 1934.

Almost all exports are shipped from Tampico. Exports to North America formerly crossed the frontier at Nuevo Laredo, but owing to the high cost of transport by land, exports to the United States are now forwarded also through Tampico.

MIGUEL GARCIA CRUZ.

## THE EXTENT OF BOVINE TUBERCULOSIS AND OF BRUCELLOSIS IN HUNGARY AND THE ORGANISATION OF CONTROL MEASURES

The extent of bovine tuberculosis is in close relation with the type of stock farming practised. The more intensive the farming, especially in dairy farming, the more cows will be found to the shed. In consequence the risk of infection is much greater, while the resistance of the animals to disease is lower, as a result of stall-feeding and of the effort made to obtain a high milk yield. This is proved from the statistics of the Budapest Abattoirs, relating to the cattle of the Hungarian steppe breed. Some decades ago, tuberculosis was practically unknown among the breeding stock of the Hungarian steppe long-horned cattle which passed the greater part of their existence on grazing lands in the open air. When this breed also was stalled, cases of tuberculosis began to be noted in numbers that showed a steady increase. Up to the first years of the present century (1899-1902), however, the proportion of animals affected, among the breeding stock of this breed, amounted only to 4 to 6.1 per cent., whereas among the coloured breeds of cattle (in particular the Alpine breeds) the proportion of animals affected was from 14.8 to 17.8 per cent. It should be noted in this connection that steers of the steppe breed were affected in the proportion of from 13.6 to 18 per cent., these steers being already stall-fed to the same extent as the breeding stock of the coloured breeds.

From the beginning of this century there was a rapid increase in infection both among the steppe cattle and among the coloured breeds, partly because stall-feeding was increasingly adopted, partly on account of the methods used to stimulate milk yields. About 1905 the infection was approaching its maximum intensity and has since remained comparatively constant, as will be seen from Table I.

TABLE I. — *Percentage of Cattle over a year old with Tuberculosis Symptoms.*

Year	Cattle of grey steppe breed				Cattle of coloured breeds			
	Bulls	Steers	Cows	Total	Bulls	Steers	Cows	Total
1905. . . . .	7.3	18.0	11.0	16.6	7.6	13.0	27.0	21.6
1929. . . . .	8.9	20.6	12.3	18.2	12.1	20.0	26.7	22.0
1930. . . . .	10.3	21.1	11.2	17.4	13.5	17.3	27.6	22.4
1931. . . . .	13.8	21.9	14.4	20.0	13.4	20.3	26.1	22.3
1932. . . . .	15.2	24.5	21.2	26.9	13.3	22.0	33.8	25.5
1933. . . . .	6.5	15.9	15.2	15.6	11.6	16.8	20.6	17.8
1934. . . . .	8.8	22.6	12.4	20.2	12.6	19.5	26.2	21.8
1935. . . . .	9.5	22.3	12.0	20.3	12.5	18.9	26.2	22.0
1936. . . . .	10.2	22.6	12.1	19.0	12.5	18.7	26.2	22.5
1937. . . . .	8.6	22.5	12.4	18.4	12.5	18.7	26.4	22.9
1938. . . . .	7.3	22.3	12.8	20.0	12.7	18.8	26.2	21.4

This table is based on the statistics of the Budapest Abattoirs: the figures shown relate to the percentage of animals over one year old, in which tuberculosis symptoms were observed. The figures of the last ten years (1929-1938) show that some degree of equilibrium has been attained in respect of the disease, that is to say, that slightly aggravated conditions in one year are balanced by a slight improvement in the following year. These fluctuations are not due to any real increase, or decrease, in the disease, but merely to the fact that, for economic reasons, sometimes older and sometimes younger animals are slaughtered. Tuberculous infection, as is well known, increases, with age; this may be seen also in the figures of the Budapest Abattoirs where, for example for the year 1929, the percentages of the cases shown in Table I are stated according to the age of the animals.

TABLE II. — *Percentage of Cattle over one year old with Tuberculosis Symptoms in 1929, by ages.*

Age in years	Cattle of the grey steppe breed			Cattle of coloured breeds		
	Bulls	Steers	Cows	Bulls	Steers	Cows
1 . . . . .	2.0	2.0	1.0	2.4	1.7	1.2
2 . . . . .	1.8	2.0	1.5	2.3	3.1	1.8
3 . . . . .	2.6	4.0	3.3	3.5	4.3	4.0
4 . . . . .	5.6	4.2	5.6	6.7	6.5	6.6
5 . . . . .	4.9	8.1	8.6	9.8	12.9	10.4
6 . . . . .	9.8	13.9	14.9	17.2	16.4	20.9
7 . . . . .	11.8	20.0	19.3	21.7	26.2	26.7
8 . . . . .	26.7	28.1	25.7	27.8	32.6	33.9
9 . . . . .	33.3	37.6	33.1	33.5	37.2	38.7
Over 9 . . . . .	41.1	38.9	35.6	40.4	39.7	39.5

For this same reason, from these statistics of the Budapest Abattoirs it is impossible to calculate the exact average percentage of the animals affected, as the older animals are usually slaughtered. Thus, the actual intensity of the infection is considerably less than would appear and cannot be determined precisely. Certain conclusions of some interest may, none the less, be drawn from the slaughterhouse statistics; the degree of infection indicated may be compared with that in other countries, and, in particular, the progress of the infection over a given period in a region may be determined with a probability almost approaching certainty.

The Budapest Abattoir statistics, based on careful investigations made each year in respect of 35,000 to 60,000 animals over a year old, point to the conclusion that the degree of infection of Hungarian cattle, in consequence apparently of special economic conditions in Hungary, remains below that in a number of other countries, and that, for more than a decade, it has stood at a peak level which is not likely to be exceeded in the near future.

It may further be noted that from 1929 to 1938, some 70,000 to 130,000 calves were slaughtered at Budapest, of which the percentage affected by tuberculosis varied only from 0.06 to 0.1 per cent.

In spite of the exactness of the statistics available, it is impossible to calculate the economic loss due to bovine tuberculosis in Hungary. It is also impracticable to determine with any precision the losses due to meat which is unfit for consumption, as the available data merely indicate the percentage of cattle in which tuberculosis symptoms have been observed. In these statistics are included: animals merely showing a primary symptom already cured or in process of cure, that is, an unimportant tubercular affection, animals in which the tuberculosis is confined to certain hardened cores in one or other organ, animals in which there is an acute and widespread form of tuberculosis, etc. Losses in meat vary considerably, however, according to the form taken by the disease. The records made by the Budapest Abattoirs indicate only cases where the whole carcass was declared unfit for food. The percentage of such animals, slaughtered at over one year old, varies, from 0.20 to 0.44.

TABLE III. — *Herds subject to State Inspection.*

Year	Herds inspected	Tuberculosis-free herds	Number of cattle in the herds tuberculosis-free
1930 . . . . .	24	0	—
1931 . . . . .	74	8 = 10.8 %	1,524
1932 . . . . .	79	17 = 21.5 %	2,939
1933 . . . . .	113	29 = 25.6 %	3,959
1934 . . . . .	129	49 = 38.1 %	6,042
1935 . . . . .	120	68 = 56.7 %	7,562
1936 . . . . .	127	97 = 76.6 %	9,089
1937 . . . . .	129	108 = 83.7 %	10,870
1938 . . . . .	124	108 = 87.0 %	10,891

Control measures were first introduced in 1930. The process of eradication by the BANG method was adopted successfully at the time on a large number of farms, as the result of the action of HUTYRA and UJHELYI, but all such efforts were frustrated by the economic confusion consequent on the world war. It was sometime after the war that control by means of the BANG method was resumed, this method consisting in eliminating all animals giving a positive reaction to tuberculin, even if no other symptom occurs. This method is not compulsory but the State gives support and encouragement to its application. According to paragraphs 520-524 of Regulations giving effect to the new law on contagious diseases No. XIX-1928, owners of herds who have signified assent are bound to apply this method for a minimum period of five years, while the

State undertakes the cost of veterinary inspection of the herds, and declares any particular herd as completely freed from the infection. This declaration is a distinct advantage to the owner, in general and is reflected in his milk sales. Particulars of the somewhat small number of herds placed under the control scheme are shown in Table III.

Measures are also in force in Hungary for the elimination of animals with open symptoms of tuberculosis. In 1938 measures were first taken for preventing contagion from cows affected with mammary tuberculosis.

Since 1933, declaration of all open forms of bovine tuberculosis has been compulsory, in virtue of paragraphs 506-519 of the Regulations in pursuance of the law on contagious diseases already referred to. If the competent Services actually pronounce an animal to be affected by any recognisable form of the disease, it must be slaughtered at once by its owner, or at least the authorities see that it is consigned to the slaughter house; if for definite economic reasons the slaughter cannot be postponed, the owner receives a payment in compensation. If on the other hand, it is possible to postpone slaughter—the maximum period of such postponement being six weeks—the animal affected by a recognisable form of tuberculosis must be branded and isolated from the other cattle. After removal of such animals, the stabling is disinfected.

In the interest of public health, all products obtained from affected animals are subjected to a sanitary inspection; in particular, meat inspection which is carried out throughout Hungary, may be regarded as a model (paragraph 92 of the Regulations giving effect to the law on contagious diseases). Sales to consumers of milk containing the bacilli of tuberculosis are prohibited, and in order to ensure a supply of pure milk for the population, measures have been taken to build up healthy, dairy herds. In addition, the milk of cows affected with mammary tuberculosis must not be delivered to consumers in any form whatever; that of cows affected by any recognisable form of tuberculosis, or suspected of being so, may be delivered to consumers only after proper heating has been carried out.

Statistics on the extent of bovine brucellosis (or contagious abortion) in Hungary are not available, and thus it is impossible to give figures showing the economic losses caused by this disease. It may however be said that it is not at present of importance on small stock breeding farms, while on the larger farms it is not uncommon.

As regards control measures, attempts were at first made in Hungary to check this disease by means of purely hygienic precautions. These measures, highly commendable in themselves, were later replaced to some extent by prophylactic inoculations as recommended to breeders. It was however proved that, although the percentage of cases of abortion was considerably reduced by the inoculations, the epidemic could not be entirely checked by these means. In the light of certain post-war researches, the negative value of the inoculation had to be recognized; it was proved by these researches that, although a reduction in the number of cases of abortion was noted in the inoculated herds, this advantage was balanced, and even outweighed, by two disadvantages, namely, an increase in the sterility of the cows and in the septicaemias affections

of the calves. Hence, since 1930, the anti-brucellosis vaccine was no longer distributed, and the measures taken for control of the disease were exclusively hygienic in character, the object being to prevent the contagion; such measures, included precautions at the time of purchases of cattle, isolation of affected animals and blood analyses, separate stables for calving and also for cases of abortion, disinfection, etc. These measures are not compulsory, and no Government measures have been introduced in this respect. The Veterinary Services of the Ministry of Agriculture, however, have already for some time past been engaged on the drafting of measures for State inspection for the control of brucellosis, but no definitive action has yet been taken by the Government.

R. MANNINGER.

## NEW TRENDS IN THE MANAGEMENT OF DAIRY CATTLE IN THE U. S. A.

In view of the economic situation of the dairy industry in the United States the costs of milk production have to be kept as low as possible. It has been realized that a very high milk production per cow, obtained by heavy feeding, is not necessarily the most economical form of production. Pasture and roughages are, as a rule, the cheapest sources of food for livestock; heavy rations of grain and concentrates tend in general to increase the production costs. Many experiment stations have therefore sought to determine whether the production costs of milk can be lowered by making more use of these cheap nutrients and by diminishing the heavy grain rations of the past.

### Increasing the proportion of alfalfa hay in the ration of dairy cows.

The great value of *alfalfa* as a feed for dairy cows has long been realized. The surface sown to alfalfa in the United States is being steadily increased, not only because of its value as feed but also because of the high output which can be obtained per unit of area and of its importance as a soil improver.

Nevertheless, the general opinion was that rations of alfalfa hay ought to be supplemented by more or less considerable amounts of grain or other concentrated dairy feed. Recently, experiments have been carried out to determine the advantages or disadvantages of feeding alfalfa, exclusively in the form of hay, as a ration for dairy cows.

Such experiments were conducted some years ago by the Kansas Agricultural Experiment Station, and it was established that 1 pound of milk can be produced for each 2.24 pounds of alfalfa hay and 1 pound of butterfat for each 61.6 pounds of hay. The milk production of the cows receiving a full ration of hay, grain, silage and pasture was approximately 40 per cent. higher than that

of the cows fed only on alfalfa. On the other hand, the cows fed exclusively on alfalfa hay showed slightly less difficulty in conception than those receiving a full ration.

Similar experiments conducted at the California Agricultural Experiment Station gave results more favorable to the feeding of alfalfa hay. In these experiments 1.7 pounds of alfalfa hay produced 1 pound of milk in the first lactation, while 1.6 pounds of alfalfa hay were consumed per pound of milk in the second lactation.

In another experiment conducted at the California Agricultural Experiment Station the animals fed with alfalfa hay only produced 88.4 per cent. as much milk and 80.0 per cent. as much butterfat as those receiving a mixed ration with full grain supply.

At the Nevada Experiment Station 1 pound of milk has been obtained for each 1.6 pound alfalfa hay consumed. The cows fed on alfalfa hay alone produced in this experiment 83 per cent. as much milk and a little less than 85 per cent. as much butterfat as the cows receiving also a grain ration.

More recently, longer and very complete experiments have been conducted under the auspices of the Bureau of Dairy Industry of the U. S. Department of Agriculture at several of its Experiment Stations and in different parts of the country. These experiments showed that the cows produced on an average 57 per cent. as much milk and 60 per cent. as much fat as they did under full-feed conditions. There is evidence, however, to indicate that the yields of cows accustomed, over long periods, to a ration consisting entirely of high quality roughage may exceed these percentages. There was a more rapid decline in daily milk yield throughout the lactation period when the cows were fed on alfalfa hay alone than when they were under full-feed conditions.

There was a certain decline in body weight of the cows receiving alfalfa hay only, but in spite of the loss of weight, they had a well-fed appearance. The long-continued feeding of the alfalfa hay ration had no detrimental effect on the fertility, breeding or calving conditions of the cows.

Some of these experiments showed that feeding on alfalfa only may result in undesirable qualities in the milk. The butterfat may give a typical sticky appearance to the butter, a defect which can however be corrected by adding silage to the ration. Feeding green alfalfa within 5 hours before milking produced a marked flavour in the milk, while this flavour was much less accentuated when hay was fed to the cows.

From cost figures and acre yields GRAVES and SHEPHERD calculated the cost of growing the feeds consumed by cows in the feeding experiments conducted at the various stations of the U. S. Department of Agriculture. The following items were compared:

- (1) roughage alone.
- (2) roughage *ad libitum* and 1 pound of grain to each 3 pounds of milk produced (full-grain ration).
- (3) roughage *ad libitum* and 1 pound of grain to each 6 pounds of milk produced (limited grain ration).

The investigators concluded from these calculations that *many farmers would find it advantageous to change their system of farming* for one in which they would keep most of their land in permanent pastures and legumes, and grow very little grain. Pasture and roughage would supply the basic ration and grain would be fed *only when the resulting increase in milk or butterfat production could be obtained at a profit*. When the prices for milk or butterfat are low in relation to grain prices the dairy farmer should feed roughage more liberally. Production will be lower when less grain is included in the ration, but the cost of the ration will be lower also – enough to make production more profitable.

The considerable differences in the results obtained in the experiments on the value of alfalfa hay as an exclusive ration for dairy cows may be attributed to the great differences in the nutritive value of hay fed. It is necessary to obtain a better quality of hay by mowing the alfalfa at the right stage of growth and by proper methods of handling the hay.

### **Making hay and silage from immature pasture grass.**

The usual method in the United States is to use certain surfaces of grassland exclusively for pasture. The surplus of grass on pasture land is rarely mowed and made into hay or silage. Hence the grass often grows more rapidly than it can be grazed, and matures, becomes unpalatable and loses the high nutritive value that it had in its earlier stages of growth.

Earlier experiments conducted by the Bureau of Dairy Industry of the U. S. Department of Agriculture showed that both hay and silage made from immature grass were *far superior* for milk-production to hay and silage made from mature grass.

Recently the Bureau of Dairy Industry conducted experiments at the Huntley field station in Montana in order to ascertain:

(a) The comparative value for milk production of hay and silage made from immature grass and fed as the sole ration for entire lactation periods.

(b) The production of cows fed exclusively on immature grass hay or immature grass silage compared to their production on a ration of grain, alfalfa hay, corn silage and pasture.

(c) The effect on the health and general condition of the animals of feeding the grass hay or the grass silage as a sole ration and for long periods.

The production of the cows on grass hay was 64.6 per cent. as much milk and 63.4 per cent. as much butterfat as their production on the full-feed ration. The cows on the grass-silage ration produced 61.2 per cent. as much milk and 61.5 per cent. as much butterfat as they produced on the full feed.

A certain decline of production could be observed during the experiments as a result of substituting alfalfa hay for grass hay and grass silage for short periods, when these feeds were not available. There was an increase again when grass hay or grass silage was again fed. These facts support the conclusion that the dry matter in the immature grass hay or silage is superior to the dry matter

in alfalfa hay that was cut at a stage of maturity in which one-half or more of the plants were in bloom.

As to health there was no difference between the cows on different rations.

These experiments show the necessity of better management of pastures, which have very often been mismanaged or neglected in the United States; *of cutting at an earlier stage of growth those pastures which cannot be grazed in time before becoming mature*; and of feeding the hay or the silage obtained from the pastures, which is a very valuable feed to the dairy cows.

### **Improving the quality of silage from grasses and legumes by better methods.**

For a long time no special attention was given to the making of silage from grasses and legumes, probably because there appeared little advantage in making ensilage of these crops when they could be made into good hay. It was, however, discovered that it was impossible to overcome the effects of unfavourable weather at harvesting time on the nutritive qualities of hay, and that in such cases ensilage was the best method for saving forage crops. Moreover, properly made silage has been found superior to the best hay in content of carotene and this has stimulated the interest in making it out of grasses and legumes.

To-day the improvement of the methods of making silage from grasses and legumes is one of the measures most essential to decrease the production cost of milk by making more and better use of roughages. Hence these methods have been the object of research work carried on in different American experiment stations.

The experiments were particularly concerned with the advantages of chopping the grasses or legumes before putting them into the silos, the different degrees of humidity of the material when put in the silo, and the advantages of adding acids or molasses to the silage. The results obtained are somewhat contradictory, but the most and recent careful of these experiments conducted by the Bureau of Dairy Industry of the U. S. Department of Agriculture at the Dairy Experimental Farm of the National Agricultural Research Center at Beltsville, Maryland gave the following results.

*Chopping* the material (cutting) resulted in various advantages. Much more material could be stored in a unit space in the silo than if the material were not chopped. Losses in dry matter were reduced, the palatability and general appearance of the silage improved. Further, it appeared to be the easiest way to put the material in the silo.

*Fresh green grass*, either alone or mixed with legumes, or fresh green alfalfa alone, made a silage that was highly palatable and, in general, possessed an agreeable odour when simply chopped before putting it into the silo, with no other treatment. The alfalfa silage, however, developed offensive odours when the dry matter of the crop was less than 30 per cent. Losses of dry matter, protein and carotene were very low and there was no moulding or rotting.

*Partial drying*, before chopping, further facilitated handling, increased the quantity of dry matter that could be put into a given space, increased the

temperature of fermentation and in most cases improved the palatability and therefore the quantity of dry matter consumed by the cows.

The *addition of acids*, as recommended by the A. I. V. (Virtanen) method, lowered the palatability of the resulting silages. It appeared, however, to favour the preservation of carotene and nitrogen. It had little effect on the losses of dry matter.

The *addition of molasses* slightly increased the losses of dry matter, protein and carotene, but somewhat improved the palatability. On the whole, this addition did not prove very advantageous, but in these experiments the molasses was not added to any grasses having a high content of moisture. In previous experiments the addition of molasses helped to preserve the nutrient matter in the silage, when the moisture content was a little too low or a little too high.

Alfalfa silage appeared to be fully equal to alfalfa hay for the production of milk, but inferior for the maintenance of the body-weight.

### Continuous Grazing.

Pasturing is the cheapest method of feeding dairy cows in a country where the price of the soil is relatively low and the cost of labour relatively high-as in the United States.

Statistics compiled by Cornell University and other agricultural colleges seem to show that the best profit to be expected from a dairy herd is made during the grazing period.

It has, therefore, been the tendency in many parts of the United States to extend the grazing period as long as possible. This has been the case particularly in the South, which is relatively backward in dairy husbandry, but which is now beginning to realize advantages of a long grazing period for dairy cows. It is true that pastures are less nutritious in the South than in the North, where the grazing period is short, but this can be corrected by finding suitable grasses and legumes for the southern climate and soil.

Extensive experiments on these lines have been carried out at Invershiel Farm in North Carolina, and the results are promising. The objective has been to provide an abundance of succulent green feed for the cows during the entire year and to make the most intensive use of the land in winter as well as in summer.

It was found that these aims could be more successfully attained by the use of *annual* crops. There are also many desirable perennials, but they can be profitably used in a continuous grazing programme to a limited extent only as their maximum periods of growth range from three to six months at the outside which means that the land must be left idle for the remainder of the year.

The annual crops which, under the conditions of North Carolina, have proved most advantageous have been: for summer grazing (Biloxi Soy Beans (grazing period: June-October), Sudan Grass (June-October), Desmodium (June-October), Johnson Grass (May-October), Lespedeza Sericea, Korean and Kobe (July-October); for winter grazing: Cold resistant oats (October-December), Abruzzi Rye (Novem-

ber-February), Beardless Barley (December-March), Bur Clover (3 varieties, December-May), Vetch with Austrian Peas (January-June), Black Medica.

By suitable rotation of these fodder crops the Invershiel Farm succeeded in extending the grazing period to a full year besides saving a great deal of labour and taking advantage of the soil-improving qualities of the leguminous crops.

At present the Invershiel Farm is demonstrating that, with the above crops (and making use of fertilizers also), it is possible to keep on an average one cow per acre with the continuous grazing method, and to reduce considerably the cost of milk production.

Thanks to all this experimental work, the dairy industry in the United States is succeeding in reducing its production costs by making increasingly efficient use of roughages, by better grazing methods, and by limiting the hitherto excessive use of concentrates and grains for dairy cattle.

## PRESENT POSITION OF THE DAIRYING INDUSTRY IN THE DIFFERENT COUNTRIES: (19) ALBANIA <sup>(1)</sup>

### Natural and Economic Conditions of Agriculture in Albania.

Situated along the western coast of the Balkan peninsula, Albania with an area of 27,540 km<sup>2</sup> (11,000 sq. miles) includes: the Ghegheria or Upper Albania, or territory of the Gheghis, and Toscheria or Lower Albania, or territory of the Toschis or the Lliapis. The country is very varied in aspect with mountain ranges, belonging to the Dinaric system, alternating with plains. There are in consequence marked contrasts of climate and vegetation; the climate ranges from the subtropical to that of the mountains of Central Europe, as one passes from the coast plain to the mountain region, which includes the Alps of Northern Albania, the central mountains and the mountainous districts of the southeastern littoral.

There are wide variations of temperature from one region to another, but no data are available for calculating the average for the whole country. The average in Tirana is 15° 5.

Albania is one of the most rainy countries in Europe, the areas of heaviest rainfall being in the west, although with some exceptions. The driest areas are in the east and southeast. Nearly all the cultivated plants suffer from drought, as the seasonal distribution of the rains is very irregular; the maximum occurs from October to January, while in the growing period, there is practically no rain.

The extent of productive lands in Albania is in all 2,873,020 ha., with the following distribution:

Pasturelands . . . . .	1,027,414 ha. or 35.70 %
Forests . . . . .	986,310 „ „ 34.30 %
Crops . . . . .	235,875 „ „ 8.20 %
Meadows . . . . .	55,575 „ „ 1.93 %
Market gardens and orchards . . . . .	10,000 „ „ 0.35 %
Lakes and watercourses . . . . .	44,530 „ „ 1.55 %
Marshes and swamps . . . . .	47,080 „ „ 1.64 %
Other lands . . . . .	466,537 „ „ 16.24 %

(1) Previous articles of this series: 1. France (November 1934) - 2. Italy (April 1935) - 3. Hungary (June 1935) - 4. Czechoslovakia (July 1935) - 5. Austria (August 1935) - 6. Switzerland (March 1936) - 7. Denmark (May 1936) - 8. Belgium (November 1936) - 9. Poland (February 1937) - 10. Bulgaria (March 1937) - 11. Latvia (April 1937) - 12. Lithuania and 13 - Estonia (June 1937) - 14. Finland (November 1937) - 15. Norway (February 1938) - 16. Iceland (June 1938) - 17. Sweden (July 1938) - 18. Romania (August 1938).

It is a characteristic feature of Albania that the pasturelands occupy so large a proportion of the productive area. According to ZAVALANI \*, these lands are distributed in the different regions as follows:

10 % and less . . . . .	Leshi, Mirdita.
11-25 % . . . . .	Dukagjini, Puka, Kopliku, Tirana, Kruja, Pogradeci, Himara.
26-50 % . . . . .	Shkodra, Jakova, Kukesi, Luma, Mati, Zerquani, Elbassani, Bilishti, Korça, Leskovidu, Permeti, Skrapari, Berati, Blora, Fieri, Lushnjan, Durresi, Shijaku, Gramshi.
over 50 % . . . . .	Mallakastira, Dibra, Kavaja, Peqini, Gjinokastira, Libhova, Delvina, Konispoli, Kurveleshi, Tepelena, Kolonja.

On the other hand, sown grassland represents 2 per cent. only of the total productive area. This small percentage is due to unfavourable moisture conditions.

The main crops are: maize (nearly 50 per cent. of cultivable lands); next wheat (about 30 per cent.), oats, rye and barley (about 10 per cent.).

Production in Albania is mainly agricultural. The few very primitive industrial enterprises found in the country, such as cheese factories, distilleries making alcohol from fruit or wine, oil mills, flour mills, cigarette factories, maize alcohol factories, etc., are for the most part agricultural industries.

The greater proportion of the exported products are of agricultural origin. Cheeses, live animals, hides and skins, olives, citrus fruits, represent about 80 per cent. of these exports. Of these, two-thirds are livestock products. In recent years there has been a considerable decline in exports, owing chiefly to the lack of organisation of sales in general, and also to the fact that certain customers who formerly made large purchases in Albania have limited their orders.

The insufficient means of communication and the prevalence of malaria are serious obstacles to agricultural progress.

### Population.

At the last census (1937) the number of inhabitants was 1,021,339, giving a density of about 37 inhabitants to the square kilometre. Distribution of population is not uniform throughout the country; in some regions the density is only 10, in others more than 100. For more than half the country, the density is about 23, a figure much below the average for the whole country. These wide divergences are to be attributed to the agricultural conditions of the different regions.

Contrary to the general opinion, Albania is not an important agricultural country, as only 25 per cent. of the population are engaged in agriculture.

---

\* ZAVALANI, Dalib (see this *Bulletin*, p. 157).

About 40 per cent. of the agricultural population are share tenants; the remaining proportion consists for the most part of small independent farmers, and of a small number of shepherds and farm workers. As the distribution of ownership of land is far from satisfactory, the native agriculture does not meet the requirements of the population. Moreover, there are no large industries in Albania capable of absorbing surplus labour. As a natural consequence of this state of things there is a stream of emigration, some workers going into other countries to work for a part of the year, others emigrating for a number of years.

### Distribution of Ownership in Land and Size of Farms.

The different classes of landowners in Albania are as follows:

- (1) The State (forests, pasturelands, waters and cultivated lands, constituting large desmesnes);
- (2) The communes (forests, pasturelands, irrigation waters);
- (3) The Church (cultivated lands, "vahuf" desmesnes);
- (4) Large landowners (cultivated lands, pasturelands and irrigation waters on latifundia);
- (5) Owners of medium-sized farms (independent family farms, belonging to the rural aristocracy, "agas");
- (6) Small land owners (small independent family farms);
- (7) Owners of small parcels of land (grasslands, vineyards, small cultivated plots, oliveyards); these are moneylenders.

Family farming is a characteristic feature of Albanian agriculture. The lands are in the hands of independent family farmers or are farmed by share tenants. State desmesnes, Church lands, lands belonging to larger or smaller owners and to the moneylenders are all split up into small farms worked by the families of share tenants.

Farms vary considerably in size; the average extent of an independent family farm varies from two and a half hectares to 7 hectares. On the other hand, a family farm on which several related families live, known as a "plluk", may be as much as from 33.2 to 38.5 hectares in extent.

### I. — Dairy Cattle Types and Breeds.

According to the latest census, taken in 1936, livestock in Albania comprised:

Horses . . . . .	67,791	head	
Asses . . . . .	68,529	"	
Mules . . . . .	9,584	"	
Cattle . . . . .	407,205	"	(including 183,256 oxen
Buffaloes . . . . .	16,453	"	and 140,542 cows)
Sheep . . . . .	1,675,368	"	
Goats . . . . .	975,017	"	
Pigs . . . . .	24,354	"	

The distribution of the kinds of livestock is shown in the following table:

TABLE I. — *Distribution of livestock according to inhabitants and area.*

Animals	Number per 1000 inhabitants	Number per km <sup>2</sup>
Horses . . . . .	66.37	2.46
Asses . . . . .	66.97	2.48
Mules . . . . .	9.5	0.31
Cattle . . . . .	398.68	14.79
including cows . . . . .	137.72	5.10
Buffaloes . . . . .	16.19	0.59
Sheep . . . . .	1,644.63	60.84
Goats . . . . .	954.65	31.73
Pigs . . . . .	23.59	0.88

Two kinds of stock farming are practised in Albania: that carried on in a single locality, or stationary stock farming, and the nomadic type: the latter, representing about one third of the whole, accounts for some 30 per cent. of the cattle and from 35 to 38 per cent. of the goats and sheep. Nomadic stock farming is a necessary consequence of the level of agriculture, as it is in this way possible to make use of extensive and somewhat poor grazing land, without means of communication. From the economic and social standpoint it is a disadvantage, as large flocks and herds are thus in the hands of a small number of persons. Encouragement of the settled kind is desirable, as thereby a larger number of people could earn a living.

One of the consequences of nomadic stock farming is that a large proportion of the products (such as cheese, hides and skins and butter), not consumed by the breeder himself and his family, is loaded on to the animals themselves and carried to the selling centres, mainly on the coast.

In the mountain regions, stationary stock farming has to rely on poor feeding and is exposed to seasonal fluctuations: grazing in summer, a little maize straw, dry leaves and poor hay in winter. On the plainland feeding is richer and more regular, but energy-producing foods are not given. In the inland valleys feeding is better, as it is supplemented by various by-products (cereal offals, etc.). In spite of all efforts, there are frequent losses of stock due to shortage of feed.

## I. — Bovidae.

### (a) BUFFALOES.

Buffaloes are very numerous in the marshy regions, and are used as draught animals.

(b) CATTLE.

In Albania, cattle breeding is impracticable on any large scale. A characteristic feature is that out of some 407,000 cattle, there are only 140,000 cows as compared with 183,000 oxen. Frequently also, the cow is not utilised for milk production, but only for reproduction and calf-feeding. The oxen are used primarily as work animals and are much in demand for this purpose.

The most common cattle breeds in Albania all come from the Illyrian cattle: the animals are very resistant to bad weather, to climate and to diseases, very docile, but give poor yields. Generally speaking, they weigh only 150 kg. and are of small build (90 cm. to the withers). The coat varies from redbrown to red-yellow, with longitudinal stripes of a yellowish white: on the inner side of the foot and thigh the colour is pale; the tuft of hair on the forehead and in the ears is also pale in colour; the horns and hoofs are black, the hide thin. These animals are valued for draught purposes. The milk yield varies considerably; 200 litres may be obtained per year, or with better feeding, from 400 to 600 litres, sometimes even more, but the average varies between 200 and 400 litres.

Good returns are obtained from cattle as draught animals. For example, 20 kg. of maize are paid, in the mountains, for the hire of a team per day. In the plains, from 3.3 to 4.5 quintals of maize are paid per team and per year.

2. — Sheep.

Sheep are the main wealth of the country. The most widespread breeds belong to the *Zackel* type. The animals are bred for milk, wool and meat, sometimes for one of these purposes rather than the others.

With the *Ruda* type, a somewhat higher yield in meat and in milk is obtained (Luma district), while the *red-headed hornless* sheep mainly yields milk (Elbassan district). Without exception, the sheep are of small build and insignificant looking; their live weight is from 15 to 20 kg. while 25, 30 or more are attained only by the *Ruda*. This breed also yields more wool, but its milk yield is lower. Apart from the milk taken by the lambs, the annual production of a ewe is about 30 to 45 kg. Analysis shows very different results for the winter milk and summer milk, and consequently for the composition of the cheeses. Thus, in summer 100 kg. of sheep's milk yield 22 kg. of cheese, but in winter only 15.

In general, 20 per cent. of the lambs die of disease and 30 per cent. are required for reconstitution of flocks; 50 per cent. are sold. Milk is fed to lambs for a longer or a shorter time in accordance with the market prices of milk; for six or eight weeks if prices are low, and some days only if prices are high.

Produce sharing in sheep farming usually consists in the practice of hiring a flock for a certain time; the products (wool, cheese, butter, etc.) are shared, and at the end of the lease, the hirer must return to the owner the number of head of sheep which he had hired. Risk of losses is usually borne by the hirer.

Lambs born during the period are shared equally, while for other products a different arrangement is made: for example, for butter the hirer owes 1 oka to the owner and the same for wool.

### 3. — Goats.

The number of goats is about 1,000,000. Goat farming represents a fairly important branch of animal production in Albania. In the case of nomad farming where goats are found side by side with sheep, the goats are used for supplying milk and cheese to the shepherds' families, while the sheep's milk is sold for consumption or is made into cheese.

## II. — Milk.

The quantity of available in Albania may be estimated at 13,500,000 litres, including cows' milk, buffaloes' milk, and sheep's and goats' milk. Sheep's milk is the most in demand.

No system of milk testing exists, the trade in milk for consumption being still in a primitive state.

In the towns milk is delivered at the house of the consumer, directly by the small milk producers, who own a few sheep, goats or cows. The milk is brought in receptacles more or less suitable for the purpose and sold by measure.

Lately (1934) BINDONI undertook an enquiry on the hygienic testing of milk for consumption delivered in Tirana. The analyses carried out show that the average fat content is 3.5 per cent. for cows' milk, 4.5 per cent. for goats' milk, and 5.5 per cent. and up to 10 per cent. for sheep's milk. The average acidity of normal fresh milk is rather high. In sheep's milk lactic fermentation is set up more slowly than in cows' milk; this is of interest, as sheep's milk which keeps longer can be transported greater distances. It is for this reason that sheep's milk is more in demand than cows' milk, apart from questions of taste. Samples examined by BINDONI have shown that the milk, especially cows' milk, is often largely skimmed; sheep's milk on the other hand is more frequently watered. The analyses have also shown that the milk contains a considerable proportion of impurities in suspension. The quantity naturally varies considerably according to the surroundings from which the milk comes, but hygienic conditions are very unsatisfactory.

Large quantities of yoghourt, a valuable health food, are consumed in Albania.

## III. — Butter Production.

The butter production is estimated at 1,400,000 kg.; it includes butter made from cows', sheep's and goats' milk. According to ZALAVANI's figures, to obtain an oka (1.28 kg.) of butter, 10 kg. of sheep's milk, 15 kg. of cows' milk, and 20 kg. of goats' milk are required.

Most of the butter is made from sheep's milk, as this butter is preferred by Albanians and keeps better. A butter-making industry in the modern sense does not exist in Albania; the process remains quite primitive.

#### IV. — Cheese Production.

Cheese production includes cheese made from the milk of sheep and goats, as well as from that of cows, that made from sheep's milk being the most important. The following types are found: *cachcaval*, *manuri* or *kephalotiri arnauti* or Albanian *fetta* cheese, and various others.

Albanian cheese is prepared, according to FILIPOVIC, by adding to the milk the rennet required to obtain curdling in 2 hours. The curd is sliced in two directions, forming squares of about 5 or 6 cm.; it is then left till the whey has turned greenish. Then the curd is filled in linen bags with a large spoon and left to drip for about six hours. The mass is then taken out and sliced into pieces of 200 g., which are placed in wooden trays and salted. The whey soon oozes out, and as a rule, to avoid contact with the air, a little whey is added, which makes the cheese keep better. This cheese has a pleasant taste. The wooden tubs used for transporting the cheese are wider at the base and can hold 10, 20 and even 50 kg.

Cheese production, which also remains very primitive, may be estimated at 3,500,000 kg., about one fourth of which is exported, almost exclusively to the United States of America, where it is absorbed by Albanian emigrants. These cheeses can hardly command sales outside Albanian circles.

#### V. — Other Derivatives.

Owing to the primitive state of the dairying industry in Albania, there are no factories in the country for the utilisation of by-products.

E. GASSER.

### MISCELLANEOUS INFORMATION

*Hydroponics*. — Hydroponics – a term analogous to the Greek term “geoponics”, which was used in the Middle Ages to denote what we understand to-day by the Latin word agriculture – is, comparatively, a very recent creation. Hydroponics may also be referred to as “Aquaculture”, “Aquiculture”, “Water Culture”, “Crop Production without Soil”, and even “Dirtless Farming” etc. Laboratory cultures of plants in liquid culture media have been known to physiologists since KNOR's time, but the possibility of the economic production of certain agricultural and horticultural crops by this method based – as it is stated – on an analytical study of the physiology and ecology of practical farm operations, has been demonstrated perhaps for the first time by Prof. GERICKE of California. Plants are grown in suitable reservoirs, basin or tanks (made of concrete, wood, sheet metal etc.) filled with ordinary water, to which are added crude chemicals containing the major, minor and trace elements required for plant growth in water. A reservoir or flat tank may provide a total water surface of 1/200 acre, and two or more reservoirs can be joined end to end. The seed-bed consists of a mat of vegetable litter – excelsior, sawdust, peat moss, etc. – spread over a portable wire netting fixable on the top of the reservoir. A system of supports is provided for the growing crop.

Reservoirs of different sizes were tried and it was noticed that the factor, size of reservoir, had a physiological significance. It was found that the yield of certain plants, e. g., tomatoes, potatoes, tobacco, bananas, was always markedly greater per unit area of the surface of the liquid medium than of soil. It is maintained that a unit volume of liquid media which contains no solids provides more water and nutrients than one in which space is occupied by solids as in the case of the soil. By hydroponics, therefore, it is claimed, it may be easier to approach the agrobiological limit of the production capacity of improved plant types than by agriculture. A field of 1/100 acre area planted to potatoes produced a yield of 24,65 bushels (1,479 lb.) in 1934. Forty pounds of chemicals were used, the retail market price of the chemical most used (potassium nitrate) being 70 dollars a ton in the U.S.A. There seems to exist experimental evidence according to which *two* crops of potatoes can be grown so as to be harvested together with

still greater yields. The second planting is intercalated when the first has passed the period of full light requirement. It is stated that two or even three crops grown together in this way do not constitute the full productive potentiality of hydroponics in regions having long seasons of favourable climate. The greatest item of cost in crop production by hydroponics is the investment in reservoirs. The high yields, however, may warrant this investment. It is rather early to predict the future economic and sociological consequences of hydroponics, but some of the advantages and potentialities of this new method of crop production may be summarised: — (1) Higher yield per unit area owing to closer plantings or denser stands; (2) More economic use of water; (3) Possible economy of labour especially as regards farm operations such as hoeing, harrowing etc.; (4) Portability of plants — which is desirable in flowers; (5) More economic use of elements by growth in water, through manipulation of factors that restrict absorption to definite growth periods; and (6) Obtaining desired compositions of plants by growth in water, through manipulations of factors that affect absorption of certain elements.

A special programme of research is under way with a view to working out the technique of growing various crops by hydroponics.

G. T. K.

TERMS OF CONSTITUTION OF THE INTERNATIONAL COMMISSION OF AGRICULTURAL INDUSTRIES. — The economic difficulties in which all nations have been involved since the end of the war have made clearly evident both the close interdependence existing between nations and the part of agriculture and of the agricultural industries as essentially regulating factors alike in the special economy of a country and in world economy.

This conception, which formerly was much criticised or at least misunderstood, is nowadays no more than a platitude which international conferences have attempted to modify but up to the present without result.

For this reason it appeared desirable in 1933 to take steps for the formation of an international organisation capable of supplying a valuable element of documentation, information and, in particular, co-ordination in respect of the technique and world economy of the agricultural industries. By co-ordination, there should be understood not only the co-ordination of the theoretical knowledge and of the practical applications in the industrial cycle properly so-called, but above all, the co-ordination of agricultural production with the requirements that spring from the industrial processing of the products.

It was with this object that the delegates of 49 Governments, meeting in Paris on the initiative of the French Government, resolved on March 30, 1934 on the establishment of the International Commission of Agricultural Industries, the Secretariat General being placed in the hands of France.

Since its establishment this Commission has given proof of an especially valuable plant of action which augurs well for its future activity. The different adhering Governments have therefore been requested to give their approval without delay to the terms of constitution of the International Commission of Agricultural Industries, since

by this means alone will it be possible for the Commission to attain its full development and to give its collaboration to the work of restoration of the economic and financial situation, on the international plane.

Terms of Constitution of the International Commission  
of Agricultural Industries.

*(Adopted at Paris on March 30, 1934, amended on June 11, 1936).*

ART. 1. — An international commission, known as "International Commission of Agricultural Industries" is established for the purpose of organising Congresses. This Commission may also propose or organise international exhibitions of agricultural industries.

ART. 2. — The Commission will consist of delegates appointed officially by their Governments, the delegation of any one nation not to exceed a maximum of six members, these delegates remaining in office until withdrawn by their respective Governments.

ART. 3. — Each member State has a single vote only, whatever may be the number of its representatives. The vote is given by the president of the delegation.

ART. 4. — The international commission elects a central bureau consisting of a president, eight vice-presidents, a general reporter and a general secretary.

ART. 5. — Former presidents of the congresses and of their executive committees and general secretaries, are entitled to membership of the commission and of the central bureau.

ART. 6. — The central bureau is the executive body of the international Commission and represents it during the periods between congresses.

ART. 7. — The central bureau meets when convened by the general secretary, on the dates and in the places fixed by the president. Resolutions are passed by a majority of the members present.

ART. 8. — The president, the vice-presidents and the general reporter are elected for each congress by the international commission and are eligible for re-election.

ART. 9. — The general secretary is appointed by the commission for the period including two successive congresses, and his mandate may be renewed. He ensures the working of the commission under the control of the president and by delegation from the bureau. He is assisted by an administrative staff appointed by the central bureau.

ART. 10. — The central bureau, in the event of decease or resignation of the president, of the general reporter or of the general secretary, makes provision for their temporary replacement in the interval between two meetings of the commission.

ART. 11. — The headquarters of the Commission and of the central bureau is fixed at Paris, at the Ministry of Agriculture. The administrative headquarters may be fixed at any other place in Paris, on the resolution of the central bureau.

ART. 12. — The international Commission meets either at Paris or at some other place in France or in another country, when convened by the president through the general secretary, in accordance with the resolution of the bureau. If required, sub-commissions may be formed consisting even of co-opted members. The Commission determines the duties and powers of these commissions.

ART. 13. — The Commission fixes its annual budget, but the budgetary year must coincide with the legal year.

The receipts will be ensured:—

- (1) by compulsory payments made by the organising committees of the congresses in accordance with article 17 hereafter;
- (2) by allocations made by the national commissions of agricultural industries;
- (3) by grants, gifts or bequests from the Governments, industries, or private individuals concerned.

An annual report on the financial management is presented to the commission, for the purposes of closing the books. A report is presented by the general secretary to a trustee in accounts appointed by the commission for the purpose.

ART. 14. — The international commission establishes the programme of the forthcoming congress together with its regulations; it draws up the list of questions which must be treated in order of priority and nominates qualified reporters to deal with them.

ART. 15. — The following are members of the congress:—

- (1) The official delegates of the different nations represented at the congress;
- (2) The representatives of the organisations of the different nations duly constituted;
- (3) Persons who have signified adhesion, conforming to the regulations of the congress.

ART. 16. — The congress fixes at a plenary meeting the places and dates of the next congress, in accordance with the proposals of the international commission.

ART. 17. — The nation in which the forthcoming congress is to be held forms a national organisation committee entrusted with the general arrangements for the congress and the drafting of suitable regulations, in consultation with the bureau of the international commission.

There shall be paid to the international commission, through and with the liability of the national committees of organisation, as contribution to the administration expenses of the international commission:—

- (1) in the year which precedes the congress a sum of 10,000 francs at the parity of 65.5 milligrams of gold of 9/10 fine (definition of the stabilised franc by the monetary law of June 25, 1928);
- (2) As payments come in, a sum equal to 10 per cent of the total of all the contributions collected by the committee of organisation of the congresses, with the exception of the contributions of donor and benefactor members for that part of their payment which exceeds the minimum contribution fixed by the regulation for the members of their category.

The national organisation committee shall, in addition, ensure the delivery to the general secretariat of the international commission of two hundred copies of all the technical publications of the congress.

Finally, from the date of the publication of the last volume of the reports of the proceedings, the committee shall forward to the general secretariat of the international commission all relevant archives or, in any case, a copy thereof.

ART. 18. — The resolutions and recommendations of the congress are considered before being put to the vote in plenary session by the international commission, which has full power to accept, amend or reject such resolutions and recommendations.

ART. 19. — The central bureau ensures the carrying into effect of the resolutions taken by the congress and, through the medium of the French Department of Foreign Affairs, notifies the governments or organisations concerned of the recommendations made.

ART. 20. — An administrative regulation, prepared by the central bureau and approved by the commission, will determine, when occasion requires, points of detail relating to the execution of the present terms of constitution.

ART. 21. — No alteration can be made in the present terms of constitution except by the international commission and on the request of delegates representing at least five States taking part in the commission, three months notice being required.

ART. 22. — For the purposes of Art. 2, the delegates of the different governments at the third international and technical congress of agricultural industries are considered as members of the commission.

G. R.

AN INTERNATIONAL BIBLIOGRAPHY OF FORESTRY SCIENCES. — The problem of the formation of an international bibliography of forestry sciences has been for a long time under consideration and in particular by the International Union of Institutes of Forestry Research. This body, after much preliminary work, published some years ago, a "Repertoire de Bibliographie Forestière", or a system of classification, which has appeared successively in German, French and English.

This classification, the work of Dr. PH. FLURY of Zurich, is also the basis of the new international bibliographical collection, established for the first time for the publications of 1937 by M. FRANZ GRUNWOLDT of the Section of world forestry economy of the Institute for Foreign and Colonial Sylviculture of the Higher School of Sylviculture of Tharandt (Saxony).

Professor FRANZ HESKE, who took the initiative in the preparation of this new bibliography, explains in his preface to the first volume the necessity, for purposes of forestry research, of an exact knowledge of all the works published in the different countries. It is thus of great advantage that a bibliographical centre should be formed, with the function of collecting all publications of a forestry character and submitting them to the fullest possible examination.

The bibliography for 1937 includes in all more than 6,000 book titles, and it may be said that the desired object, *viz.*, that of including all the forestry bibliography

without omissions, has already been attained by the first series of this publication. As the aim was to include all the publications without exception, it was impracticable to make summaries or reports in addition to the titles. The editor has confined himself to giving the titles of the various works with the necessary bibliographical indications.

The order of subjects follows, in its main lines, the system established by M. FLURY. There is, however, no attempt at a detailed subdivision by subject, and instead a geographical subdivision is adopted; the publications of general character are placed in each group under the heading "International". The absence of a detailed subdivision by subject is balanced, to some extent, by an alphabetical table of contents which is found at the end of each part. So far there have appeared the annual collection for 1937 and that for the first six months of 1938; after the appearance of the volume for the second half of 1938 the bibliography will be published every quarter, as a regular supplement to the review "Forstliche Rundschau" (Verlag J. Neumann - Neudamm u. Berlin).

S. v. F.

### BOOK NOTICES \*

DEL BO, Professor Carlo, *Corso di agraria*. Biazzi, Milano. 1938, 357 pp. figs.

[The subject of this book is agriculture and agricultural economics. The course in agriculture takes up 278 pages and is divided into two parts. The first includes the following chapters: plants (elements of anatomy and vegetal physiology; climate and climatic factors; soil; preparation of soils (removal of stagnant water, distribution of soil in plain and mountain regions, etc.); cultivation (methods of work); soil fertilisation (dressings, chemical fertilisers, organic fertilisers) irrigation; crop rotation and association; propagation of plants: field work.

The second part deals with the various farm crops—cereals and leguminous plants, oil-yielding plants, root crops, fodder plants, tree and bush crops.

The course in agricultural economics extends to 79 pages, one part dealing with farm accounts and another with the fixed capital of the farm.

The work is readable and illustrated with several drawings].

D. K.

BIGNAMI P. *Il grande canale Muzza, la rete delle rogge derivate e il territorio irrigato*. Ulrico Hoepli, Milano, 1939. 453 pp., 45 illus. 2 maps.

[Although more than half the irrigable land of Italy benefits from this improvement, great possibilities of irrigation remain, especially in combination with fertilisation. It is hoped to secure along these lines an ever increasing degree of self-sufficiency in food production.

---

\* Under this heading are included short synopses of books received for review.

Surface irrigation is effected almost exclusively by open canals. Installations for artificial rain are still too costly and suitable only in special conditions.

Irrigation is practised most extensively in the Po plain and, in particular in Lombardy. In this region it has been the backbone of a highly developed agriculture for hundreds of years. One example of the irrigation works is provided by the Muzza canal, southeast of Milan, with which the author of this book deals in detail. This canal and its irrigation system was constructed by the city of Lodi and the landowners concerned. It receives its water from the Adda, a tributary of the Po. It is 38.7 km. long but its ramifications reach a total length of 1,283.4 km. The area irrigated includes lands, formerly very poor and permeable, which in the course of centuries have been improved as a result of intensive stock-raising and of the consequent plentiful natural fertilization. Without irrigation, however, the land would soon fall back to its primitive, almost infertile state.

In the nine separate parts of his book the author describes: (1) Land and climate; (2) Source, temperature and chemical composition of the irrigation water; (3) The Muzza canal with construction details; its outflow and control; (4) The ramifications of the Muzza canal; (5) The region irrigated; (6) The organisation of water distribution; (7) Land ownership and economic conditions in the irrigated region. In the eighth part the author gives an account of the origin and historical development of the Muzza canal and the legal position. The ninth part deals with outstanding questions to be solved in the future.]

H. J. H.

ZAVALANI Dalib, Dr. agr., *Die landwirtschaftlichen Verhältnisse Albaniens*. Berichte über Landwirtschaft, 140 Sonderheft, Berlin 1938. Verlagsbuchhandlung Paul Parey. 151 pp. 6 maps, graphs.

[This work gives a competent account of agricultural conditions in Albania based on researches conducted by the author during many years in the country. It is all the more valuable because it is the only work that deals so completely with Albanian agriculture.

The first of its two parts describes the natural and economic conditions of Albanian agriculture. The conformation of the country, the climate and soil, the history and political organisation, the population, land ownership and the size of farms, mode of tenure and leasing of livestock, the means of communication, marketing and sales, credit and agricultural wealth are all dealt with.

In the second part, the author studies the different forms of farming. (1) Forms of agriculture, the crops cultivated, silviculture and the area under forest in various regions, the area of pasture in the different regions, meadows, the extent of cultivated land in the various regions, gardening, special crops, horticulture, marsh, lakes and wet lands, uncultivated and arid lands. (2) Crops and, rotation and methods of working arable land; a description of the forms of agricultural exploitation. (3) Animal husbandry, exploitation of animals and pasture; this chapter indicates the importance of stock raising in Albania, the methods of feeding, the distribution by zones of livestock numbers, sheep, goat, cattle, pig and poultry raising, apiculture and sericulture; the upkeep of animals for work, oxen, horses, asses, mules and finally, pisciculture are also

dealt with. (4) The forms of grazing, settled farming without transhumance, shifting stock raising and large scale nomadic stock raising; under these heads, the author deals in particular with Kelmeni, Vurgu, Luma and Berzeshita.

The 6 maps constructed by the author form a very valuable contribution to the work. The first illustrates the altitudes of the country, the second the zones of cultivation of the various plants, trees, and climate, the third shows the administrative divisions and communications, the fourth indicates the density of population, the fifth illustrates the relative importance of the cultivated crops and classifies the various zones according to their agricultural wealth; the sixth indicates the extent of the various crops by zones.

The author's endeavour to provide almost complete statistical material for a country hitherto much neglected deserves recognition. A summary in English, French, Spanish and German and a large bibliography are given at the end of the book.]

E. G.

GOIDANICH Prof. Dott. G., BORZINI Dott. G., MEZZETTI Dott. A., VIVANI Dott. W., *Ricerche sulle alterazioni e sulla conservazione della pasta di legno destinata alla fabbricazione della carta, eseguite nella R. Stazione di Patologia Vegetale di Roma. Ente Nazionale per la cellulosa e per la carta. Rome, 1938. 513 pp., figures and coloured plates.*

[The question of wood pulp preservation is very important in view of the appreciable losses that now occur. Hence the search for the best method of preserving the pulp from its preparation until it is finally transformed into paper.

Several countries are closely interested in this question. Outside Italy the paper manufacturing industries of North America, Sweden, Norway, Germany and other countries are beset by serious technical and economic difficulties and attempts are made to reduce the losses caused by the deterioration of the raw material during storage. These losses are reflected in a lower yield and quality of colour pulp and subsequently in a less uniform paper. The loss is particularly serious in paper intended for periodical publications. Factories which work mainly with wood pulp and which for economic reasons are obliged to hold stocks of pulp to be drawn upon when production falls off, can hardly maintain a constant balance between the woody mass which emerges from the stripping machinery and that absorbed by the paper-making plant.

This book gives an account of the work of Professor GOIDANICH and his collaborators on the biology of wood fungi and on the best methods of preserving the pulp, with the object of eliminating the substantial losses now suffered by the paper industry.

The book contains nine chapters. The first (*Notes on the production of wood pulp in Italy*, by G. GOIDANICH) gives some information on pulp production in Italy from poplar wood. Methods of cultivation and poplar improvements are described followed by notes on the working up of the raw material and the preparation of pulp which is pressed to yield an easily transportable product containing, according to the drying methods adopted, about 70 per cent. of water. The most serious deterioration of the pulp occurs during storing in warehouses, silos or in piles in sheds.

The second chapter (*The microflora of wood pulp*, by G. GOIDANICH) describes methods of analysing the wood pulp for the isolation of blueing micro-organisms. After

a study of the blueing micro-organisms of pulp in Italy, the author gives a methodical description of fungus forms, five of which appear to be new.

The third chapter (*Microflora of wood pulp, Bacteria*, by H. MEZZETTI) studies the bacterial forms isolated from wood pulp. The harmful effects of these are open to doubt and are certainly not as serious as those of the fungi. The author outlines the research programme to be followed on wood pulp bacteria.

Chapter IV (*Description, artificial reproduction and classification of spots*, by G. GOIDANICH and W. VIVANI) contains some considerations of the nature of the spots, their propagation and the damage they cause. A classification of 38 fungi is given in order of harmfulness, the most dangerous being *Haplosporella Vivianii* and *Phialophora Richardsiae*.

The fifth chapter (*Physiology and the biological action of the blueing fungi*, by G. GOIDANICH and W. VIVANI) is divided into three parts. The first deals with environmental factors influencing the vital and metabolic processes of the blueing fungi and, in particular, the temperature, humidity and aeration of the substrata, the chemical composition of wood pulp, the reactions of the substrata, and light. The last part of the chapter deals with the reciprocal action of the various micro-organisms in the wood pulp and gives many examples of phenomena of antagonism on which biological control methods are based.

Chapter VI (*Etiology and epidemiology of deterioration* by G. GOIDANICH, A. MEZZETTI and W. VIVANI) is also in three parts. The first deals with the origin, preservation and diffusion of the germ and the second with the various phases of the microflora in the different methods of treatment. The observations made show that when the wood pulp emerges from the mills it contains no fungi or only a small proportion, clear water also contains little but the air is relatively rich in them. Hence the pulp is contaminated during preparation by spores from the air. The third part considers the action of a bleaching solution made of bisulphite of soda as it has been observed that raw material treated with sulphite is more easily attacked by fungi.

Chapter VII (*Action of antiseptics in artificial substrata on the development of micro-organisms of wood pulp*, by G. BORZINI) contains some general considerations on the choice of antiseptics, the various concentrations to be tested on the wood pulp and the methods and substances used. The microbic flora examined comprise 15 fungi and 2 bacteria already described in Chapter II. The antiseptics which have given the best results in preventing or impeding the development of microbic flora are beta naphthol, sodium dinitrophenol, potassium bichromate, sodium fluoride, zinc chloride, boric acid and borax.

Chapter VIII (*Antiseptics in the preservation of wood pulp; practical trials in paper mills*, by G. BORZINI and W. VIVANI) consists of three paragraphs. The first deals with the experiments made by the "Cartiere Tiburtine" at Tivoli with wood pulp in lumps, involving the application, with or without a bisulphite of soda bleaching solution of the most promising antiseptics in the optimum proportions.

Borax (at least 1 per cent. of the fresh pulp), sodium fluoride (0.5 per cent.) and zinc chloride (0.9 per cent) gave excellent results. The second paragraph deals with the antiseptic treatment of pulp in granules not treated with bisulphite. At the end of about

seven months, the action of boric acid, Beta naphthol, carbonic acid and, in particular, salicylic acid antiseptics was seen to be insufficient even in maximum concentrations. The last named even encouraged deterioration. On the other hand, other antiseptics, including sodium fluoride zinc, fluorsilicate, borax sulphur dioxide, sodium fluoride sulphur dioxide gave good results. The third paragraph discusses the industrial application of these antiseptics.

Chapter IX (*General conclusions on the researches*, by G. GOIDANICH) indicates how and to what extent, industry can benefit from the researches.

A summary in Italian, French, English and German is given at the end of the book].

### NEW ASPECTS OF NITROGEN FIXATION AND CONSERVATION IN TROPICAL SOILS

One great difference between temperate and tropical soil conditions is the slowness with which, in temperate countries, the processes such as the disintegration of parent rocks, formation and depletion of soils, plant growth and the like take place, and the rapidity of the same processes in the tropics. The average high temperature and soil, the intensity and distribution of the annual rainfall, the activity of microflora in the formation of organic substances vary considerably in the arid and humid, and the denuded and the covered areas of the tropical regions. While, in the parts covered with vegetation, a cooperation between these factors may enrich the soil in humus and organic matter to the extent of forming pockets of bogs and swamps, in barren, arid regions the disintegration of uplands and mineralization of plant residues may result in a deficiency in humus in the arable areas. The hot countries, for the most part, are known to suffer from such a deficiency.

Nitrogen fixation and nitrogen economy are, therefore, very important problems in tropical and sub-tropical countries. For tropical as well as temperate soils, the main sources of this element are the same: atmosphere, dead matter, and nitrogenous manures. The "nitrogen cycle" worked out in temperate countries holds good, in the main, for tropical countries also. Where the differences lie has recently been shown by the Indian school of workers led by Prof. DHAR of the Allahabad University. However, in order to appreciate better the theoretical and practical significance of the data given in the following paragraphs, it may perhaps be worth while to state briefly our current conceptions on those parts of the "nitrogen cycle" on which new light has been thrown during the last ten years or so. Our new knowledge concerns mainly the fixation of atmospheric nitrogen and its conservation in the soil. It is well known that the nitrogen from the atmosphere is fixed both directly and indirectly. Large quantities (a total of about 250,000 tons of nitric acid a day according to certain estimates) are fixed as oxides by electrical discharges in the atmosphere and conveyed to the soil as nitric and nitrous acids by rain, nitrates and nitrites being formed in the soil. Nitrites, as the nitrogen of organic matter and ammonium compounds, are frequently of little direct use as food for plants, and hence they must first be oxidized to nitrates. This is done, as BERTHELOT concluded and as WINOGRADSKY (1895) and BEIJERNCK (1901) proved, by the action of

certain bacteria, the process being called nitrification, a term first used by GEORGE MOORE. The nitrogen of the proteids is converted by bacteria like *B. mycoides*, *B. fluorescens* and fungi such as the *actinomycetes*, into ammonia which combines with the  $\text{CO}_2$  produced to form carbonate of ammonia which in its turn is oxidized by the action of *Nitrosomas* into nitrites, and these again by *Nitrobacter* into nitrates, ready for immediate absorption by plant roots. The amount of nitrogen fixed by bacteria increases by 30 per cent if certain protozoa are present, although protozoa feed on bacteria. Atmospheric nitrogen is also fixed by certain bacteria such as *Bacillus radicola* living symbiotically with certain plants, chiefly *Leguminosae*. Altogether, the symbiotic nitrogen fixation is believed to enrich the soil by some 50-100 lbs per acre under normal conditions in temperate countries. The optimum conditions for nitrification may be roughly summed up thus: (i) suitable food for the microbes and fungi, *i.e.*, potash, sulphates, phosphates, carbon dioxide, lime, etc., (ii) basic material to combine with the nitric acid, (iii) absence of very strong light which may paralyse and eventually kill the nitrifying bacteria, (iv) sufficient moisture, (v) suitable temperature, and (vi) sufficient oxygen. Certain soil bacteria which fix atmospheric nitrogen and form nitric acid can work, however, only in the absence of oxygen, so that there must be other bacteria in order to help in removing the oxygen from the soil. Finally, various other species of bacteria bring about denitrification, and by their agency considerable quantities of gaseous nitrogen are returned to the atmosphere. All this shows that the importance of bacterial activity is preponderant in the processes of nitrification, ammonification and denitrification in the soil.

The study of the bacterial activities may be said to have begun with BERTHELOT in France, who found that sterilized soils do not take up nitrogen from the air, whilst unsterilized soils do, and he concluded that assimilation was due to micro-organisms. Recently, Prof. DHAR of the Allahabad University, India, using completely sterile soil and mixing it with certain energy-rich materials under sterile conditions, observed nitrogen fixation in light and concluded that soils can take up nitrogen photochemically from the air. It is stated that very large amounts of nitrogen are fixed in this way under natural conditions in the soil. Just as photosynthesis in plants, which is an endothermal reaction, takes place in sunlight or electric light when aided by the energy obtained in plant respiration, so nitrogen fixation according to the endothermal reaction  $\text{N}_2 + \text{O}_2 = + 43.2 \text{ Cal.} = 2\text{NO}$  can occur in the dark—though more vigorously in sunlight or bulb-light if energy is made available by the oxidation of different energy-rich materials by air. The latter reaction is verifiable experimentally (6,10) and DHAR and SUNDARA RAO (9) actually obtained 9 mg. of nitrogen fixation per gram of cane sugar oxidized (*i.e.*, about 23 mg. of nitrogen fixed per gram of carbon oxidized) in the sunlight by passing sterile air through solutions of carbohydrates containing ferrous hydroxide, cerous hydroxide or sterile soil in the complete absence of bacteria. It is important to appreciate this, as the implications of recognizing that light plays a part in soils analogous to the part it plays in carbon-assimilation in plants may lead to a revision of ideas on some of the most important problems in soil economy in hot countries:— such as

nitrogen fixation and the bacterial situation, nitrogen fixation and manuring with carbohydrates, fats and certain organic acids, nitrogen conservation in the soil, use of composts, carbon-nitrogen ratio, alkali soils and their reclamation, etc.

### (I) Nitrogen fixation and carbohydrates – Influence of light.

#### (a) EXPERIMENTS IN BASINS.

DHAR and co-workers first thoroughly investigated the changes occurring in the total and available (nitric and ammoniacal) nitrogen contents of the soil on the addition of different quantities of molasses to the soil. It is well-known that, in normal conditions, the nitrates and ammonia together rarely account for more than one per cent of the nitrogen in the soil (18). On the other hand, the molasses contains about 70 per cent of carbohydrates and traces of nitrogen, potash, phosphorus, etc. The experiments were conducted in dishes, basins and experimental plots, and in the fields. In the laboratory experiments, both sterilized and unsterilized soils were used, and these experiments as well as those in the experimental plots were carried out both in light and dark. To quote a typical experimental result: if 1 kg. of soil, preferably having a low nitrogen content, is properly mixed with a definite weight of carbohydrates, e.g., 50 gm. of starch in basins (diameter 26 cm.), adjusting the moisture content to 20 per cent. and if one set of basins is exposed to sunlight daily for eight hours and the other kept in the dark, it is found that there is more nitrogen fixation in light than in the dark. The nitrogen, carbon, moisture contents and bacterial counts of this experiment are given in table I.

Nitrogen fixed per gram of carbon oxidized is equal to 7.8 mgm. in light and 3.13 mgm. in the dark, i.e., more in light than in the dark even though the *Azotobacter* count in light is much less than in the dark. As there is more evaporation of water in light than in the dark, distilled water (16 per cent) was added every day to the exposed basins and once every three days to the basins kept in the dark. Another varying factor was temperature, which was higher (34°-48°) in the case of the exposed set than in the case of the dark set (28°-38°). Experiments were therefore repeated at different temperatures ranging from 11° to 60°, and the results obtained confirmed the conclusions given above.

The phenomenon has also been studied in artificial light from a thousand-watt gas-filled tungsten filament lamp placed at 30 cm. above the basins, with results which can be similarly interpreted. Using completely sterile (bacteria-free) soil with as low a nitrogen content as possible and mixing it with energy materials other than starch—which was used in the typical experiment mentioned above—under completely sterile conditions, nitrogen fixation has been observed in bulb-light as in sunlight. Definitely concordant and most promising results have been obtained by adding carbohydrates in the form of molasses, cane sugar, glucose, glycerol, mannitol, dextrin, fructose, maltose galactose. The amounts of nitrogen fixed per gram of carbon oxidized in light and dark are given in Table II.

## (b) PLOT AND FIELD TRIALS.

Experiments were also carried out to see whether photochemical fixation of atmospheric nitrogen holds good under field conditions. Size of plots used was 6 ft. by 4 ft., and the plots that were not to receive sunlight were covered with wooden planks on raised bricks. These plots were watered once a week while, for reasons already noted, those exposed to sunlight were watered more frequently, *i.e.*, every four days. The soil in plots of the two sets was dug up simultaneously. *Azotobacter* counts, ammoniacal nitrogen, nitric nitrogen, total nitrogen and total carbon estimations were made at regular intervals. The amounts of nitrogen fixed in light and dark per gram of carbon oxidized of three of the substances mentioned above are given in Table III (\*).

TABLE III. — *Nitrogen fixed per gram of Carbon oxidised (Fields).*

Substances	Rate of application (in tons per acre)	Nitrogen fixed per gm. of C oxidized, in light (in mgm.)	Nitrogen fixed per gram of C oxidized in dark (in mgm.)
Starch . . . . .	8	16.5	5.9
Glucose . . . . .	10	14	7.27
Molasses . . . . .	20	8.9	3.96

Further, the experiments carried out with varying quantities of molasses showed that application of this substance at the rate of 3, 10, 20 and 40 tons

(\*) These three tables are taken from a circular letter addressed by Prof. N. R. DHAR to different Soil Laboratoires.

per acre to normal soil exposed to air and sunlight, and turned over once a month, resulted in the fixation of 112, 270, 493, and 605 lb. of nitrogen per acre respectively. Addition of 493 lb. of nitrogen per acre of soil is stated to be equivalent to the addition of 22 mgm. of nitrogen in the first nine inches of the soil (6).

Another conclusion drawn from the results obtained on the addition of molasses is with regard to the available nitrogen (sum of ammoniacal and nitric nitrogen). The percentage of available nitrogen which, unlike that of total nitrogen, is much greater in tropical than in temperate soils, is maintained at a high level as the nitrogen fixed by the application of carbohydrates is easily converted into available form. It would be well to know whether this increased percentage of available nitrogen reflects on the plant growth and yield. It is not known whether systematic tests on a statistical basis were carried out in every case but some general results may be given. The two or three crops which seem to have been under trial were sugarcane, rice and wheat, and it was found at two places (Pusa and Madras) that molasses when added to the *growing* crop produced no beneficial effect. KERR, on the other hand, on applying 10 tons of molasses per acre in the Bundaberg farm in Queensland, is reported to have obtained 14.4 tons more of sugar cane per acre than in the control (without molasses), whereas CRABTREE working in the Fairy Mead farm in Queensland did not find any beneficial effect with molasses. BOOBERG (3) points to the advantage of applying molasses *before* planting both in the case of rice and sugarcane, and arrives at the conclusion that molasses can be economically utilized as a fertilizer(\*). Recently, an increase of yield to 36 per cent has been reported at the Government Farm, Shehjehanpur (India), on applying 10 tons of molasses per acre *before* planting. The increase in yield of the same crop in Madras is reported to be even more, *i.e.*, 40 per cent (8). In 1936, DHAR conducted similar trials with paddy and found that by adding 3 tons of molasses per acre of land which was also molassed the previous year, and by digging and watering the land once in every 20 days in the hot months of May and June, 32.3 maunds (1292 kg.) of grain and 85 maunds (3400 kg.) of straw were obtained per acre as against 20.5 maunds (820 kg.) of grain and 38 maunds (1520 kg.) of straw in the control plots respectively. More recent work on the subject by SETHI, BATHAM and NIGAM in the United Provinces and by MIRCHANDANI in Bihar (India) seems to give further support to the conclusion that molasses adds nitrogen to the soil and improves the yields of sugar-cane, rice and also of wheat (6).

## (2) Nitrogen fixation and cellulosic substances – Influences of light.

Although celluloses cannot be utilised directly in nitrogen fixation, the importance of the decomposition of celluloses as a source of energy for nitrogen-fixing micro-organisms has been pointed out by eminent investigators (2,13, and

---

(\*) For details, *vide* "Miscellaneous Information" p. 197 of this issue.

16). The action of cellulose-decomposing bacteria or the symbiotic action of nitrogen-fixing and cellulose-decomposing bacteria is considered essential for this process of nitrogen fixation. It is also recognized that high temperature can be beneficial for cellulose decomposition (22). ALLEN, ABEL and MAGISTAD working on two lateritic acid soils (pH 5.0) in an 81 day experiment in cans, and mixing these soils with variously divided pineapple trash (stumps and leaves) containing about 34.05 per cent of cellulose and 45.70 per cent starch, found that the addition of the trash stimulated the growth of bacteria, fungi and actinomycetes, that there were no appreciable differences in the amounts of ammoniacal nitrogen but that the greatest average amount of nitrate nitrogen occurred in the soil containing coarse trash and the least in soil containing finely divided trash (1). It is not quite clear whether the cans were placed in the light or in dark, but it seems that they were sealed. The experiments in dishes carried out by DHAR and co-workers suggest that cellulose substances like dry leaves, filter paper, sawdust, cow dung, etc. cause nitrogen fixation when mixed with soil with or without molasses and exposed to sunlight, or diffused light.

Without reproducing here the numerous observations made, it may suffice to state the general result that this nitrogen fixation is greater in sunlight than in diffused light. The observations show that in either case, in sunlight or diffused light, the process goes on with a variable intensity, but the nitric, ammoniacal and available nitrogen were never below the original nitrogen content of the soil for the 5-8 months during which the estimations were made periodically. The results of the experiments in which the above substances were used mixed with small amounts of molasses (5 gr.), indicate that there is more nitrogen fixation than in the former case. Tests in open and covered plots seem to be carried out with only one of the cellulose-containing substances, the cow dung, which was applied at the rates of 34, 48, and 68 tons per acre. It was found again that in open plots there was marked nitrogen fixation in sunlight even in 33 days, whereas in the covered ones there was little or no fixation (7). These experiments firstly confirm that - as is well-known - the cow dung as a manure adds to the soil its quota of nitrogen, and secondly bring to light the fact that it enriches the soil by fixing atmospheric nitrogen, thanks to the oxidation of its celluloses, pentosans, lignin, etc. which takes place in sunlight and at high temperatures common to tropical countries. It is stated that, with cellulosic materials, the available nitrogen is always less in the beginning than that originally present in the soil. This appears to be the essential difference in the mechanism of fixation of atmospheric nitrogen by celluloses and carbohydrates. With the latter group of substances, the available nitrogen is always greater throughout the whole time of the process. In any case, in all these experiments the carbon has been found to decrease with time due to its oxidation.

If these experiments show the importance of cowdung manuring, they also bring to the forefront the whole problem of manuring with cellulosic substances (dry leaf, wood fibre, straw, etc.) and suggest the need of revising our theory of the use of composts, especially in hot countries. Straw, leaves and other plant residues have been utilised in the preparation of artificial farm-yard manure or compost from time immemorial, though it is practically only during the last two

decades that the subject has been studied scientifically. While almost all the investigators appreciate the value of composts in enriching the soil in plant food, a few show a certain scepticism with regard to the practicability of their preparation, as in some cases losses of nitrogen seem to have been noticed. In composting the main aim is to conserve the total nitrogen originally present in the materials and add it to the soil along with the carbon of the compost. The results obtained by DHAR and co-workers show that it is more profitable to add the cellulosic and carbonaceous substances direct to soil *before* they are composted. When the plant materials, which should not be in large excess, are added to the soil direct and ploughed under before the rainy season they are considerably decomposed and oxidized under the influence of sunlight and heat. Consequently they not only add to the soil the nitrogen they contain, but also increase the nitrogen content of the soil by fixing nitrogen from the air. It is further claimed that the method is found to improve not only the nitrogen conservation capacity but the moisture retention, the humus content, the carbon-nitrogen ratio and the general tilth of the soil. We shall come back to the more important of these points at a later stage.

### (3) Nitrogen fixation, and fats and sodium salts of fatty acids.

#### LABORATORY AND PLOT EXPERIMENTS.

It is generally believed that fats are oxidized in the soil with great difficulty. DHAR and co-workers used 1 kg. of soil in their experiments and added 20 gm of butter, and found that nitrogen fixation took place in sunlight as well as in dark. The percentage of the nitric nitrogen remained constant in the 'exposed' experiment and decreased in the 'dark' one, but that of the ammoniacal nitrogen went on increasing during the two months or so covered by the observations made. At this period the available nitrogen content is definitely greater in the 'exposed' than in the 'dark' experiment. The figures for total carbon content and the number of *Azotobacter* in millions per gram of dry soil show an increase in the two experiments.

Sodium salts of various acids, such as sodium tartrate, sodium citrate, sodium oleate, sodium stearate and sodium palmitate, were added in amounts varying from 10 to 13 grams to 200 gm. of soil, and nitric N, ammoniacal N, total N, total C contents were determined as in the other experiments; the heat of combustion of the acid per gram was also determined in the case of the first three salts. The results show that the greater the energy liberated from the oxidation of the salts, the greater the amount of nitrogen fixation. With the first three salts, there is more nitrogen fixation than with the others.

Tests seem to have been conducted also in plots (4' x 4') with ghee and butter; two kg. of ghee were added to one plot and two and a half kg. of butter to another. The results confirm the main conclusion that in the oxidation of fats energy is liberated and this is utilized in the fixation of nitrogen from air.

#### (4) Carbon-Nitrogen ratio.

Microorganisms are known to play an important rôle in establishing a definite relationship between the two most important elements, carbon and nitrogen, in the soil. The ratio C : N varies with the type of soil. Broadly speaking, in the humid tropics it is 10 but seems to be higher in drier tropical and subtropical regions (21). It is generally believed that the combined nitrogen existing in the soil can form nitrate only if the C : N ratio is not greater than 10 to 11, unless the carbon of the carbonaceous matter is not readily available, *e. g.*, in the case of butyric acid and alcohol (22). If the proportion of readily available carbon is greater than the above ratio, the excess is oxidized to CO<sub>2</sub> and the nitrogen remains as a complex protein; on the other hand, if nitrogen is in excess, the nitrogenous substance is changed into ammonia and nitrate.

DHAR and co-workers studied the influence of temperature on the C : N ratio in soils by maintaining a sample of garden soil at 80°-85° for nearly two years. They found that the C : N ratio appreciably increased as the heating continued, and concluded that the higher the temperature of the soil the higher the ratio. This is in general agreement with observed values of C:N ratio in different parts of the world. Further, they contend that the C : N ratio is not controlled by the energy requirements of microorganisms but it is regulated by the ease with which proteins, amino acids, ammonium salts, etc. are oxidized by air, aided by light, bacteria and catalytic agents in the presence of carbonaceous substances. It is stated that when the carbohydrates and cellulosic substances are present in large amounts, the proteins, amino acids and ammonium salts present in the soil are protected from oxidation and are conserved in the soil. When they are oxidized to a great extent, ammonification, nitrification, etc.—which are also mainly oxidation processes—accelerated by sunlight, high temperature, catalysts, inductors, bacteria, etc., become prominent in the soil. In these processes, an appreciable loss in nitrogen in the gaseous state takes place (6).

#### (5) Denitrification.

The term *denitrification* generally designates the complete reduction of nitrates to atmospheric nitrogen and oxides of nitrogen, and not simply the reduction of nitrates to nitrites and ammonia or assimilation of nitrates by microorganisms. The two latter processes, it is believed, do not involve any loss of nitrogen from the soil. It is known, however, that nitrogen in the gaseous state is lost from soils when conditions are favourable for oxidation (14, 19, 20). The loss of nitrogen in this process may be as much as double the amount of nitrogen absorbed by the plant grown in the soil. But even greater losses of nitrogen are known to occur when a manure is composted under aerobic instead of anaerobic conditions. Experiments, conducted at different places show that the oxidation processes are more vigorous in soils with crops than in uncultivated soils. Hence, denitrification is most intense in cropped soils. Difficulty

is often experienced however, in explaining the precise mechanism of all the types of nitrogen losses from the soil which has been under cultivation for 20-30 years (18).

The various chemical reactions studied by DHAR and co-workers in light and in dark lead these investigators to explain the mechanism of the loss of nitrogen in the gaseous state from the soil. In the processes of ammonification and nitrification taking place in the soil or in solutions, ammonium nitrite is produced. Solutions of ammonium nitrite readily decompose into nitrogen and water by increase of temperature or exposure to sunlight or bulb-light. The formation of ammonium nitrite from ammonium salts or proteins requires oxygen and that is why this type of denitrification is facilitated by increased soil aeration and also soil acidity, as nitrous acid also undergoes decomposition, with an accelerated rate in light, according to the following equation:

That the loss of nitrogen (in the gaseous state) from the soil is due to the formation of ammonium nitrite is supported by certain manurial trials. The soil loses nitrogen in this way much less when manured with sodium or potassium nitrate than when manured with ammonium sulphate or organic nitrogenous manures, because with the latter class of compounds the unstable ammonium nitrite is formed.

With varying quantities of one of the above-named compounds which is known to form ammonium nitrite and thus cause denitrification, *viz.*, ammonium sulphate, tests were made in plots with and without the application of energy-rich materials. In the first set of experiments ammonium sulphate was added at the rate of 17.325 kg. of nitrogen per acre, in the 2nd 34.65 kg. of nitrogen per acre, in the 3rd 69.30 kg. of nitrogen per acre, in the 4th 138.6 kg. of nitrogen per acre, and in the 5th 277.2 kg. per acre each. The results indicate that a certain retardation of nitrogen loss is noticeable in the molassed plots. For example, with 138.6 kg. of nitrogen as ammonium sulphate per acre of land, the loss of nitrogen amounts to 34.2 per cent. in the absence of molasses, whilst with molasses it is 27.1 per cent.; and with 277.2 kg. of nitrogen, the loss is 43.9 per cent. without molasses and only 17.9 per cent, with molasses.

Similar comparative sets of tests conducted with ammonium sulphate, with cow-dung, green leaves and molasses also support the conclusion that the nitrogen loss is reduced by the addition of these cellulosic and carbohydrate substances.

#### (6) Alkali soils and their reclamation.

The alkali lands, of which large tracts exist in the tropics, are known to have the following main defects: (1) Alkalinity (pH of 10.8); neither *Azotobacter* nor nitrates can exist in alkaline soils. (2) Deficiency in calcium compounds and exchangeable bases. (3) Low nitrogen and carbon contents. (4) Impermeability

to water. (5) Feeble activity of microflora. The conversion of alkali soils into normal soils is a very serious problem. DHAR and co-workers who studied the causes of a normal soil in India becoming alkaline, also investigated the more important problem of the possibility of the economic conversion of alkaline land into normal soil. These studies included that of the pressmud, an easily transportable substance, which is turned out at the rate of 300,000-400,000 tons a year by the Indian sugar factories. The pressmud contains calcium salts and when mixed with alkaline soil is found to reduce effectively the pH of the soil. Molasses appears to possess the same property. Studying the effects of oils in the form of oil cakes (linseed, mustard, rape and "Neem" oil cakes) and cellulose materials, they found that the alkalinity of alkali soils is neutralized by the addition of all these substances. In field trials, molasses or a mixture of molasses and pressmud have been found excellent, even for bad alkali soils. The alkali soil which is a sodium soil is converted into a calcium soil which is normal, when a mixture of pressmud and molasses or molasses alone (which contains 2 per cent of lime) is added. These results have been confirmed in different parts of India (Mysore, Bombay, Bihar and the United Provinces) with applications of molasses varying from 1 to 10 tons per acre, and it is said that a fairly good rice harvest can be obtained from reclaimed areas where this crop completely failed in previous years, or where, in some cases, no vegetation of any type existed. On land reclaimed by molasses, it has been found possible to produce rice crops for two years or more successively without any further applications of molasses.

### General considerations and conclusions.

The substances dealt with in the foregoing account are all energy-rich, and from the results of the numerous experiments carried out by the Indian investigators it appears that, in the oxidation of all such substances on the soil surface, nitrogen fixation is a general phenomenon. The importance of the bacterial activity in the soil is not denied—in fact a certain amount of adaptability is noticed in *Azotobacter*, the optimum temperature for the vital activities of which is found to be 35° for the tropics as versus 25° for cold countries—but enough evidence has been obtained to show that nitrification is not mainly a bacterial process. In tropical countries the nitrogen changes in the soil are due more to light and heat than to bacteria. Eighty per cent of the nitrate accumulation is known to take place in the upper 3 ½ inches of the soil. Meteorological observations indicate that the soil temperature in summer months in the tropics cannot be much below 50° even at this depth, so that very few bacteria can exist during this season in tropical soils. Yet the amount of nitrates in the soil is said to be at a maximum in summer. This, together with the observed photo-oxidation of amino acids to ammonia, of ammonium salts to nitrites, of nitrites to nitrates (not described here for want of space, and to avoid giving too many chemical details) and the fixation of atmospheric nitrogen, seem to indicate that sunlight and high temperature play a more important part than bacteria in the nitrogen economy of the soil in the summer months.

It need hardly be said that the above factors may represent some of the main elements in the potent natural process of recuperating soil fertility spoken of by many workers. The art of agriculture, on the other hand, has existed about 7000 years from its humblest beginnings (4) and one can say that man, consciously or unconsciously, has contributed considerably to soil destruction: witness "The man-killed hills of China" and the Sahara Desert (5). There should be a perfect balance between the nitrogen requirements of the crops we harvest and the natural processes that recuperate fertility. As to India—where the importance of this natural process has been recently thrown into relief—the fact that there are large annual increments of nitrogen in the soil has been established in all the provinces, and quantitative estimates have been made in Bombay, Central Provinces and the Punjab (17). That a balance between the two forces has been reached is demonstrated by the observed low—but stable—level of fertility of Indian soils maintained year after year perhaps through centuries (in respect of the alluvial soils of the United Provinces, 10 centuries (12)) in the absence of manuring and despite the annual losses of nitrates which, broadly speaking, are greater in tropical and subtropical than in temperate soils.

Of the three groups of substances, carbohydrates, celluloses, fats and acids, described above, molasses is obviously the more thoroughly worked out substance from the standpoint of the nitrogen economy of the soil. This is probably because approximately half a million tons of molasses are produced annually in India and their economic utilization is an important problem for that country. While it is true that molasses-manuring may prove of value to all sugar-producing tropical and subtropical regions, the possibilities of a more extensive utilization of the other groups, *viz.*, celluloses, fats and acids, should not be overlooked. A thorough study of acids from this point of view may be highly important, for Palestine, for example.

The photochemical interpretation of the nitrogen transformations in the soil is obviously a departure from the known procedure of interpreting these changes in temperate soils. This is not the first time, however, that particular hypotheses in biological fields have pointed the way to new creative advances; agricultural scientists should keep an open mind on the school of thought led by DHAR and his co-workers. Treatises on tropical soils should deal adequately with these phenomena. Should the claims put forward be substantiated by results obtained under different conditions of soil and rainfall in the tropics, manuring with carbonaceous and cellulosic substances and especially with molasses will become highly important in agricultural practice in tropical countries. A stage has been reached when all the practical possibilities of the findings should be investigated. It might thus be ascertained whether immediate results on a practical scale, can be obtained, and if so, whether judicious collaboration on the basis of these findings with the natural recuperative forces would tend, in the long run, to steadily raise the low cropping values of tropical soils.

## NEW DEVELOPMENTS IN DAIRY CATTLE BREEDING IN THE UNITED STATES

Several years have elapsed since the dairy cattle breeding world was amazed by news of record productions established by American dairy cows. It was to be expected that within a reasonable length of time, such outstanding animals would influence the production level of the dairy cattle population throughout the country.

This, however, has not been the case. The influence of these highly productive cows and their offspring has been confined to a relatively small number of outstanding pure-bred herds, and the level of the general dairy herd has shewn only a small rise during the past decades.

It is true that the principle of production breeding became rapidly popular throughout the dairy cattle industry. The Dairy Herd Improvement Association movement gave the average dairy farmer facilities for developping his herd towards an increase standard of productivity. The number of such associations and the number of cows tested by them has increased almost continuously from when the first cow-testing scheme came into operation in 1906. Nevertheless, the use of the records obtained by this testing work was lacking in efficiency. Even the better breeders limited themselves to selecting their animals for breeding purposes out of good producing cows, and did not care about the capacity of the animals to transmit good production to their offspring.

This was less true for pure-bred herds, where production testing was combined, from its inception, with the animals pedigree. Very probably, the rapid progress shown by production records of pure-bred herds was mainly due to this factor.

Considerable progress has been achieved thanks to the investigations made into the bull's capacity to transmit a certain production level. This study led to the discovery of methods of proving dairy sires and the different bull indices, described in a previous paper. Proving dairy sires has since been largely applied in the United States on the basis of records obtained by the Dairy Herd Improvement Associations and later by the Breed Associations. The results of bull provings are published by the U. S. Department of Agriculture in the lists of proved bulls.

### **Herd analysis.**

While the breeding work has since been based, as far as bulls are concerned, on the transmitting ability of the animals, this has not been the case with the cows. It was generally considered sufficient to know the actual milk and butterfat production of the cow, as shown by her records.

In this direction, however, an almost revolutionary change has recently occurred.

Under the direction of Prof. S. J. Brownell the Dairy Extension Service of the Agricultural College, of Ithaca, N. Y., now examines the heredity of production of complete herds, both bulls and cows. These herd analyses are based on the principle that the transmitting ability of the animal is independent of its actual production level. This principle is not new and agrees with the general genetic findings made during recent years. What is new, however, is the introduction of this principle into the general practice of breeding dairy cattle and the method employed for this purpose.

Herds belonging to the dairyman who applies for an analysis of his stock are analysed by this Extension Service on the basis of all the records available going as far back as possible. They are reduced for this purpose to equivalents for a 305 day lactation period of 6 years old animals milked twice a day. The results of this analysis are given in the form of a pedigree chart showing in the horizontal columns the cow families composing the herd, and in vertical columns, the bulls with their respective daughters (see examples enclosed). To make the representation more easily comprehensible the production records are given in different colours according as they show increases or decreases, compared with their dams. The whole gives a very clear picture and permits, even at first sight, a judgement as to the transmitting ability in a cow family or in a bull, according to whether the blue or the red colour predominates either in the horizontal or in the vertical columns of the chart.

In addition to this pedigree, details of the results of the bull tests (average production of daughters, results of dam-daughter comparisons, number of dam-daughter pairs compared, number of pairs showing increases) are given with graphical representation of the bull's transmitting abilities.

The picture of his herd, as furnished by the herd analysis, shows the breeder the cow families and bulls of which good production inheritance may be expected. By selecting his breeding animals from such families and from the offspring of these sires, the breeder will have a high degree of probability of obtaining highly productive cows in successive generations.

The contrary will be the result if he selects his animals from families showing a considerable spread and irregularity in their production records. That this very often happens, even with highly productive cows clearly indicates the absence of linkage between the transmitting ability of a given animal and its actual production level.

These herd analyses, of which the methods have been worked out by Prof. S. J. BROWNELL, have furnished the breeder with the practical means of selecting animals for transmitting ability, and the results so far obtained are very promising.

### **Artificial insemination.**

Naturally, animals belonging to highly productive strains, together with a stable transmitting ability, will greatly increase in value.

Although the cow may have the same probability of influencing the production level of the offspring, the importance of the bull is considerably greater

## EXPLANATION OF FIG. 1.

Each group of five figures corresponds to one cow.

The three figures in the middle of each group signify (from top to bottom):—

- (i) number of the cow;
- (ii) average milk production;
- (iii) average fat production in lb.

The figure on the left of each group gives the number of records (r) on which the averages are based; the figure on the right gives the average fat percentage.

If the cow's number is given in blue (in Fig. 1, in heavier type), her butterfat production is above the average of all daughters of the bull, if in red (*i. e.*, in Fig. 1, if in lighter type) *vice versa*.

The colour (in Fig. 1, the nature of the type) of the production figures shows the increase or decrease in production as compared with the cow's dam. (Blue — here heavier type — indicates increase, red — lighter type — decrease).

(N. B. — In the three original Charts by the Cornell University — *Vide* Fig. 1, 2 and 3 — Sire D, poor transmitter of productivity, is given in red type and Sires C and E, good transmitters, in blue type. In Fig. 1, 2 and 3, Sire D and Sires C and E are given in heavier and lighter types respectively).

FIG. 2. — Range in production of sire's daughters compared to their dams. Range in production indicates sire's dependability as transmitter of a certain level of production.

N. B. — In the original Chart by the Cornell University the two plain arrows in the above figure are blue and the dotted one is red (and plain).

because of the greater number of offspring which he is able to procreate. This fact emphasizes the necessity of making the greatest possible use of bulls with proved ability of transmitting high production levels and belonging to families

showing a certain concentration of genes responsible for high production. In this respect artificial breeding has an important place in the future American dairy cattle breeding programme.

By artificial insemination the number of offspring of an outstanding bull can be greatly increased.

As far as the technique of the artificial insemination is concerned, American science has so far not created anything essentially new. The American artificial breeding methods are based on the experiments made in the Soviet Union, the results of which were confirmed by the results obtained in the United States (2).

In this field, as with regard to the herd analyses, the methods of introducing the artificial insemination into the general breeding practice, merit particular attention.

An artificial breeding circle was founded in June 1938 in the State of New Jersey and was soon followed by a second organization of the same kind in the State of New York.

These are pioneer organisations which admit that their activities are "a demonstrational project, the possibilities of which have not been fully proved".

Nevertheless, they are of considerable interest and the participation of breeders in the project is extremely encouraging. This participation is greatly favoured by the spread present, of certain venereal diseases in cattle. It is hoped, that these diseases may be controlled by avoiding the direct contact between animals though the use of artificial insemination.

It may be of interest to the dairy breeders of other countries to have some details about the make-up of these pioneer-organisations. The Pioneer Cooperative Dairy Cattle Breeding Association (the organisation in New York State) began work on November 14, 1938. It has a minimum number of 500 cows; the total number of cows admissible under its regulations is 1200. Herds belonging to the associations should be located within a 20 mile radius of the Association's headquarters. The Association, which closely collaborates with the New York State and the New York State College of Veterinary Medicine College of Agriculture possesses two outstanding bulls belonging to the best production strains of the country. One is an 8-year old tested bull, and the other a young bull. Semen is collected from each bull on alternate days. Therefore one ejaculation is available every day, which - diluted - can fecundate several cows. When a cow comes in heat, the owner telephones to the headquarters of the Association and the Veterinary of the Association then calls at the farm in order to perform the insemination. If the first service is unsuccessful, a second and a third will be performed without charge. The Veterinary of the Association also examines the member's cows for pregnancy and is authorized to treat them if they show any breeding trouble. A certificate is issued by the Association after each successful breeding attempt, stating the bull's name and number, which in the case of a pure-bred animal can be attached to the Service Certificate of the application for registry in the herd-books.

For these services, the member-breeder pays a membership fee of 5 dollars and an assessment of 5 dollars per cow at the time when the breeding is per-

FIG. 3. — Chart showing individual dam-daughter comparisons for different sires. Upward arrows indicate increased production; downward arrows decreased.

N. B. — In the original Chart by the Cornell University, the plain arrows in the above figure are blue and the dotted arrows are red (and plain).

formed. These fees have been fixed provisionally; after further experience it will be possible to make permanent financial arrangements.

### Performance registry.

The breed associations realized many years ago that the registry of animals in herdbooks on the basis of their pedigree only was not sufficient to bring about an increase in their production level. Supplementary registers have therefore been established within these organisations, called Advanced registry or Registry of merit. In addition to purity of breed, certain standards of production are required for being thus registered. From this registry of performance, however, animals remained excluded which did not belong to one of the established breeds, in the strict sense of this word, i. e. if their ancestors were not registered in one of the herdbooks, which have been closed for many years to the entry of non-descendants of herd-book animals. Animals remaining excluded form any performance registry constitute 97 per cent. of the total dairy cattle population of the country.

On the other hand, it has been recognized that the inheritance of producing characters has nothing to do with a given breed or with the characters of this breed, even if – as is true – best results were obtained in the past with pure-bred animals. The scientific considerations and the practical experiences leading to this opinion, have been dealt with in a previous paper. Little effort has been made, however, to introduce such concepts into general breeding practice.

An attempt in this direction now is being made by the American Dairy Cattle Club; as announced in this Bulletin, the Club has opened a performance register for all dairy animals meeting the requirements for registry, irrespective of breed.

The Advisory Council of the Club met recently in New York, in order to establish the general requirements for entry in the Club's registers, which hitherto were only of a provisional character. The discussions of the Advisory Council are very interesting and afford a good view of the present state of opinion in regard to these matters.

The result of the Council's meeting was the establishment of a scale of four orders of recording. The possibility of higher orders in the future has been left open. The minimum requirements for recording are given in terms of 6-year-old, 305 day, twice a day milking record, and for bulls in terms of the so-called American Index based on such records. (The American Index is founded on the concept that the average production of a bull's daughters lies exactly between the production of their dams and the production-transmitting ability of their sire).

The production records established for recording in the club's registries are the following:

	Females	Males (Indexes)
Order I	A production record of not less than 305 days' duration or two daughters with records of not less than 300 lb. butter fat each . . .	
Order II	350 lb. butter fat . . . . .	375 lb. butter fat
Order III	400 » » » . . . . .	400 » » »
Order IV	425 » » » . . . . .	425 » » »
	450 » » » . . . . .	450 » » »

As a general rule, recording in a higher order is only allowed if the animal is a descendant of parents registered in the next order below. An exception is made in the case of bulls having a 10-pair index of 450 lb. of butter fat or over. Such a bull is eligible for recording in the 2nd Order without any pedigree. The question of the possibility of recording bulls without pedigree in the 3rd order has been referred to the next meeting of the Council.

The American Dairy Cattle Club accepts all production records made under American Dairy Science Association rules which give the necessary guarantee for an exact and trustworthy execution of the tests. The animals are initially classified on the basis of the first production record for females and of the first 5-pair index for males. The final classification is made for females on the basis of all her production records when she ceases test, and for males on the basis of his final or first 25-pair index (whichever is completed first), provided that such production records or indices exceed the former records or indices used for initial classification by 10 per cent. or more.

Herd analysis, the introduction of artificial breeding into general breeding practice, and performance registry for good producing animals independent of any consideration of breed characters, are important steps forward. They make available to dairy cattle breeders the most recent results of scientific experiment in the field of dairy cattle breeding. As the average American cow does not pay, the problem of increasing the average production is, therefore, a very urgent one.

In a lecture delivered at the Farm and Home Week of New York State, recently held in Ithaca, N. Y., Prof. S. J. BROWNELL remarked that we live in a revolutionary period in the field of dairy cattle breeding. Breeding for performance was formerly the aim, but we are now entering the period during which more attention will be paid to the ability of the animal to transmit its production to its descendants. This new challenge may help to raise the general production level of American dairy cattle.

## PRESENT POSITION OF THE DAIRYING INDUSTRY IN THE DIFFERENT COUNTRIES: (20) YUGOSLAVIA <sup>(1)</sup>

### Geographical survey.

The present Kingdom of Yugoslavia, constituted after the war of 1914-1918, includes the former Kingdom of Serbia, with the territories of Bosnia, Herzegovina, Dalmatia, the Vojvodina, Croatia, Slovenia, Slavonia and the former Kingdom of Montenegro.

The area of Yugoslavia is 247,542 km<sup>2</sup>, and the population —consisting of Serbians, Croats and Slovenes—is 15,173,600, according to the statistics of the census of December 31 1936. In spite of a considerable increase during the last few years, *viz.*, from 48 inhabitants per km<sup>2</sup> (the figure of the previous census) to 61, the density of population is still low. The most populous areas are Croatia and Slavonia, with Slovenia and the Vojvodina. Old Serbia is more thinly populated, and the density is lowest in Southern Serbia.

The greater part of the country is situated in the Balkan peninsula, but the northern districts belong to Central Europe and in particular to the Pannonian basin. Yugoslavia may thus be considered both as a Balkan State and as a State of Central Europe. It lies between 41° and 47° Lat. N. and 14° and 23° Long. E. of Greenwich. Although it is a continental country, its situation in the South East of Europe, and its possession of the Dinaric coast region with Salonica, makes it a Mediterranean country also. It has 1,600 km. of Adriatic coastline and some 2,400 km. of land frontiers. The districts near the sea have warm summers and mild winters; the average temperature in January is 6° C., in July 24° C. The rainfall is very abundant; the maximum for all Europe is reached at Boka Kotorska. In the interior, that is, in the greater part of the country, the climate is continental: there are great daily and yearly fluctuations, the average temperature in January being -2° C., in July 20° C. Rainfall diminishes from the south-west towards the north-east.

*Administrative organisation.* — Yugoslavia is divided into “banates” (each named from the river which traverses it, except for the coastal banate which includes the greater part of the Dalmatian coast); Drava, Sava, Urba, Zeta, Drina, Morava, Danube, Vardar, and the Coast banate.

<sup>(1)</sup> Previous articles of this series: 1. France (November 1934) — 2. Italy (April 1935) — 3. Hungary (June 1935) — 4. Czecho-Slovakia (July 1935) — 5. Austria (August 1935) — 6. Switzerland (March 1936) — 7. Denmark (May 1936) — 8. Belgium (November 1936) — 9. Poland (February 1937) — 10. Bulgaria (March 1937) — 11. Latvia (April 1937) — 12. Lithuania and 13. Estonia (June 1937) — 14. Finland (November 1937) — 15. Norway (February 1938) — 16. Iceland (June 1938) — 17. Sweden (July 1938) — 18. Romania (August 1938) — 19. Albania (April 1939).

*Agrarian reform.*— After the union of Yugoslavia, the agrarian position was completely reorganised. In partitioning of lands, personal merit was taken into account: thus ex-service men had preference in the re-distribution. The large landowners received compensation for the lands which they were obliged to give up. By the Constitution of Vidovdan, which regulated the new system of land tenure, the lands were distributed by families. An internal movement of migration was thus set up, certain families changing their district in order to settle on new lands.

As a result of this agrarian reform, large estates no longer exist in the North of the country, but are still to be found in Southern Serbia. Speaking generally small holdings predominate: 68 per cent. have from 0.01 to 5 ha., 20 per cent. 5 to 10 ha., and scarcely 12 per cent. more than 10 ha. The distribution of rural ownership in Yugoslavia is shown in the following Table.

TABLE I. — *Farms in Yugoslavia grouped according to size.*

Size in ha.	Number of farms	Percentage	Total area
0.01 to 0.50 . . . . .	158,904	(8 %)	43,410
0.50 „ 1 . . . . .	175,532	(8.9 %)	135,760
1 „ 2 . . . . .	337,429	(17 %)	514,372
2 „ 5 . . . . .	676,284	(34 %)	2,287,570
5 „ 10 . . . . .	497,237	(20 %)	2,873,155

Total . . . . .	1,985,725	—	10,645,980

### Economic tendencies.

The population is for the most part rural, mainly engaged in arable and stock farming; the products, owing to the diversity in climate and soils, are very varied.

As agriculture is the principal resource of the majority of the population (80 per cent.), special attention is naturally given in the new State to this branch of the national economy. A number of measures have been taken for the organisation of the production and protection of farmers.

Scientific management applied to production and the standardisation of farm products have helped to increase farm incomes. The encouragement given to the co-operative movement, with the organisation of co-operatives for purchase, sale and production, has done much towards lowering cost prices and facilitating the sale of farm products. The establishment of credit institutions and of a

State Agricultural Bank for the sole purpose of making loans to farmers, the promulgation of numerous Decree-Laws and Orders relating to the protection of farmers, have all had the effect of preventing farm indebtedness at usurious rates.

The result of all these measures has been to increase the output of Yugoslav agriculture with an improvement at the same time in quality, and to raise the standard of existence of the rural population.

### I. — Dairy cattle types and breeds.

Stock farming is an important branch of Yugoslav agriculture. The following table (taken from the *Monthly Crop Report and Agricultural Statistics*) shows the variations in the live stock numbers during the years 1920, 22, 24, 26, 28, 30, 32, 34 and 1936

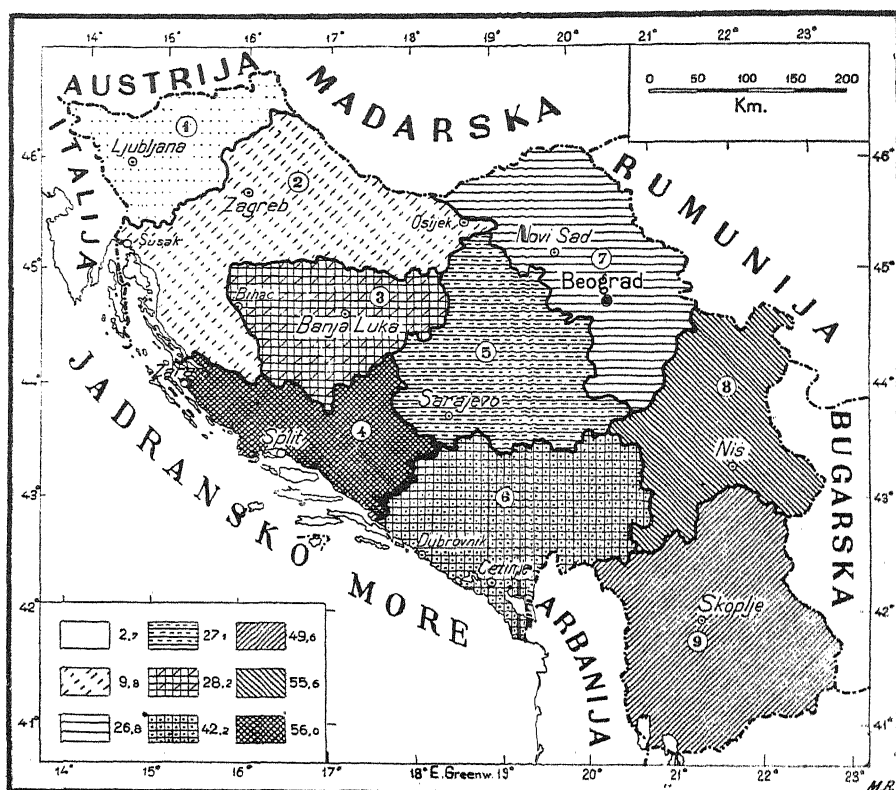

TABLE II. — *Live Stock Numbers (1920-1936).*

Year	Cattle	Horses	Asses	Mules	Sheep	Goats	Pigs	Buffaloes
1936....	4,079,729	1,216,085	123,461	17,987	9,568,338	1,905,993	3,126,241	37,217
1934....	3,989,947	1,205,865	120,034	17,678	8,867,685	1,881,126	2,791,592	38,929
1932....	3,812,208	1,156,997	114,719	16,449	8,510,441	1,871,618	2,863,177	38,704
1930....	3,812,172	1,161,235	106,944	15,843	7,953,139	1,731,430	2,923,862	37,487
1928....	3,654,261	1,109,246	103,528	15,165	7,722,247	1,750,006	2,662,790	32,116
1926....	3,706,019	1,116,858	96,298	14,551	7,932,845	1,721,263	2,806,182	31,519
1924....	3,784,267	1,053,875	89,779	14,190	7,618,708	1,718,368	2,517,955	28,626
1922....	4,058,419	1,043,528	86,036	15,002	8,461,504	1,801,409	2,887,020	31,938
1920....	4,951,339	1,062,343	84,182	18,091	7,002,124	1,552,555	3,349,504	31,470

In proportion to its area and population, Yugoslavia holds an important position specially as regards small live stock, in European countries.

	per km <sup>2</sup>	per 1,000 inhabitants
Horses . . . . .	5 ( 4,88)	82
Cattle . . . . .	16 (16,46)	270
Sheep . . . . .	39 (38,66)	630
Goats . . . . .	8 ( 7,70)	126
Pigs . . . . .	13 (12,63)	206

The different kinds are distributed irregularly in the different territories. The largest proportion of the horses, nearly half the total, occurs in the Vojvodina nearly half the cattle in Bosnia-Herzegovina; three million sheep in Serbia, and as many in Bosnia-Herzegovina.

MAP. — Number of sheep per km<sup>2</sup> in the different banates.

## (I) Bovidae.

## (a) CATTLE.

The native breeds belong to two types: *Bos brachyceros Illyricus* ADAMETZ and *Bos Taurus primigenius*. The former is undoubtedly the older type and the more numerous.

The indigenous breeds are found both pure and crossed. The most widely diffused, representing 80 per cent. of the total cattle, is the Illyrian, the indige-

nous breed found in the western part of Yugoslavia and extending northwards as far as the Save and southwards as far as Albania. It is of small size, and the coat varies greatly: it may be white, yellow, red and even ebony black, but always of one colour and seldom striped. ADAMETZ distinguishes three types according to colour: the light coloured Illyrian, the brown and black, and the striped. The live weight of the cows is from 250 to 350 kg. (sometimes 100 kg. only). The annual milk production varies from 900 to 2000 litres with a high percentage of butter fat.

The Illyrian breed belong to a primitive stock, which was not intensively bred, now mainly found in the poor regions of the Karst. It is a very hardy breed with few special requirements. With proper attention and good feeds, the cows yield abundant milk with a very high proportion of fat. To this group belong all the indigenous short-horned sub-breeds, of Croatia, Slavonia, Bosnia, Herzegovina, Montenegro, Dalmatia, Serbia and Macedonia.

In addition to the indigenous Illyrian cattle, there are also the indigenous steppe cattle.

These are found especially in Syrmia, Vojvodina and Posavina, and are typical descendants of the Hungarian steppe cattle.

The Posavina cattle represent a degenerate type of this breed known as « gulja ».

The steppe cattle are also used as work animals; crossings of the Illyrian and of the steppe cattle have given rise to the various sub-breeds: *Colubara*, *Morava*, *Bihac*, *Tuzla*, which almost without exception resemble the steppe cattle in colour, while in their conformation they show the influence of sometimes one, sometimes the other breed.

With a view to the improvement of the indigenous breed, the Zillertal-Tuxer, the Mölltal, the Pinzgau and the Simmental breeds have been introduced into Croatia-Slavonia, and the Montafon breed into the Karst districts. In Slovenia, there are already tracts of country where there are found clearly marked breeding stocks of acclimatized breeds, in Carniola: Simmental, Montafon and Pinzgau; in Styria: Murboden, Lavanttal, Mariahof and Montafon; in these parts stock breeding has reached a high degree of perfection, and the products are in demand on the world markets, especially for the quality of the meat. In the Vojvodina the steppe cattle predominate, crossed with the brown mountain cattle and with the Simmental. In Bosnia-Herzegovina the Mürztal were first introduced, and then the Wipptal and the Pinzgau. In Serbia the Mürztal and the Mariahof were introduced, but had no decisive influence; later the Allgäu, Montafon and Simmental were also introduced, so that there is a great diversity of breeds.

It will be seen that the picture presented by the breeds, sub-breeds, crossings, etc., is somewhat complex. A decisive influence, however, has been exercised only by the Pinzgau, the Simmental, the light-coloured and gray brown mountain cattle. The tendency of the breeding is towards a distinct separation between slaughter stock and dairy cattle.

## (b) BUFFALOES.

Buffaloes are bred only in Southern Serbia, their numbers are now hardly 37,000 head.

## (2) Sheep.

Sheep farming is of great importance in Yugoslavia; owing to the natural and economic conditions sheep farming is widely diffused and at the same time carried on by extensive methods.

GRAPH I. — *Number of sheep in the different banates in 1929-1932.*

The number of ewes in the different banates is sometimes very small. Thus in the Drava banate, according to the figures of 1929-32, there are only 2.7 sheep per square km., and in the banate of the Sava 9.8. In other banates the numbers are higher, in the Danubian 26.8 sheep per square km., in the banate of Drina 27.1, of Urba 28.2, of Zeta 42.2, of Vardar 49.6, of Morava 55.6, in the Coast banate 56, as shown on the accompanying map on page 186 (1).

(1) Dr. Athanase MITROVIĆ, Source of wool and improvement in quality in our Kingdom. *Arhiv. Ministarstva poljoprivrede*, Belgrade, 1934. (In Yugoslav.)

Graph I shows the number of sheep in each banate, compared to the total number existing in the country. For the period 1929-1932, these percentages were as follows: Drava 0.45, Sava 4.6, Urba 7, Drina 9.3, Danubian banate, 9.4, Coast 13.7, Zeta 15, Morava 17.6, and in the Vardar 22.1. The banates poorest in sheep are thus Drava and Sava, and those with the largest numbers Vardar, Morava, Zeta and Coast. In these last the sheep form the only wealth of the inhabitants, out of which they pay their taxes, provide for the upkeep of their animals and for family needs. In many districts, sheep farming is an additional source of income compensating for the scanty income obtained from the remainder of the live stock. Hence sheep are mainly found in districts where the cattle numbers are small: in 1929-1932, there were some 22.5 cattle per square km. in the banates poorest in sheep (Drava, 24.2 head of cattle, Sava 21.4), while the contrary was the case in the banates where sheep are most numerous (Coast banates, 9.6 cattle per square km., Morava 11.9, Zeta 12.4 and Vardar 12.7).

The relation between the sheep and cattle for each banate is shown on the accompanying graph II.

GRAPH II. -- *Relation between the number of sheep (I) and cattle (II) for each banate.*

Many regions, with large tracts of waste lands on which clearing is impracticable, are utilised profitably for grazing of flocks. Excellent conditions for sheep farming occur in the wooded and hilly regions.

Breeds of sheep include the *Zackel* breed or *Wallachian* sheep with its numerous sub-breeds, accounting for some 90 per cent. of the sheep numbers, the *Cigaja* and its crossings with the *Wallachian* sheep and with the *Merinos*, and finally the *Seebodner* (derived from the *Kärntner* and the *Bergmasco*) in small numbers.

The *Zackel* is bred for the triple purpose of milk, wool and meat. The quantity of milk supplied by the ewes is from 35 to 60 litres, corresponding to a yield in cheese of from 8 to 12 kg. The sheep vary in weight from 25 to 45 kg.

The *Cigaja* is bred mainly for wool and meat, the live weight being between 45 and 50 kg.

The sheep belonging to the *Seebodner* breed are raised for milk, wool meat. Their live weight is from 50 to 60 kg.

### (3) Goats.

The red breeds of Bosnia are preferred, they are not easily distinguishable as to coat, height, etc. They all belong to the Central European type of goat (*Capra prisca*). Their milk yield is much higher than that of sheep (120-180 litres). The skins are utilised for the manufacture of carpets, stuffs, etc.; the meat is dried (*castradina*) or salted.

Latterly the *Saanen* goat has been introduced.

## II. — Milk Production.

Although stock breeding is fairly well developed, there is no real dairying industry in Yugoslavia except in the northern plains. As stock farming is of the extensive type, the milk is mainly used for feeding calves. There are no markets in the true sense. The chief markets such as those of Belgrade, Agram, Ljubljana and Novisad are of the peasant type. Nearly all the towns have a large rural "hinterland", which supplies them with milk, butter and cheese.

Larger towns such as Agram and Ljubljana, however, already obtain milk handled on modern lines. Dairies are also found at Osijek, Marbourg, Novisad, Serajevo, while at Belgrade the milk passes directly from the producer to the consumer. The small farmers bring the milk into the town, direct to houses and to market.

The following figures will give an approximate idea of the milk production (some 3,000,000,000 kg.):

1,900,000 cows yielding an average (ranging from 900 to 2000) of 1350 litres milk . . . . .	=	2,565,000	l.
6,600,000 ewes yielding an average of 30 litres milk . . .	=	198,000	l.
1,500,000 goats yielding an average of 150 litres milk . . .	=	225,000	l.
		<hr/>	
		2,988,000	l.
		<hr/>	

Milk recording has been introduced with success in certain districts, but it is not yet applied on a large scale.

Yugoslav dairying is slowly but surely adopting modern technique. Active support is given by the State, but the dairy farmer is hampered by various legislative difficulties and by inadequate means of communication. It seems probable, however, that an important dairying industry will eventually be organised.

### III. — Butter Production.

The quality of the butter, coming as it does mainly from the farms, is not entirely satisfactory. It is made both from cows' and sheep's milk, the latter mainly in the south of Serbia and in some parts of Central Serbia and from of Bosnia.

In these districts, in addition to butter made from fresh sheep's milk, another type is made from the residues of the making of kachkaval cheese. This butter is mainly exported to the Near East, where it is used in cooking, mixed with mutton fat, under the name of "Siberian butter". Some 120,000 kg. of butter in all are exported, especially to Turkey, Greece and Albania.

Internal consumption is small, as lard and olive oil are largely used, especially on the Dalmatian coast. The dairy butter made in northern Yugoslavia is of good quality, but is not in demand except in the towns, principally in the north. The butter made on the State desmesne "Belje" should be specially mentioned; it is excellent and is used to supply the capital. Milk and other dairy products are also supplied from this estate.

### IV. — Cheese production.

There is a great range of cheeses made either from cows' milk, or from sheep's or goats' milk, or from mixtures of cows' and sheep's milk. The best known cheeses are: Kachkaval, Trappist, Trafnik, sheep skin cheese, smoked cheese, Somborer cheese, etc.

Of less importance are the imitations of Emmental, Gorgonzola, and of other foreign cheeses which are made with varying success. Latterly the making of melted cheese has been introduced, apparently with success.

More modern methods are used in cheese production in the north of the country, where there are five modern factories making Emmental, Trappist cheese, melted cheese, Edam and Liptau. In Bosnia, even before the war the making of Roquefort and Liptau cheeses on an industrial scale had been attempted and the antiquated methods of making native sheep's milk cheese were abandoned.

Among the best known cheeses is the *kachkaval*, made with sheep's milk. The centre of the production of this cheese, which is made also sometimes with cows' milk, is southern Serbia, in the Pirot region.

The following description of its manufacture is taken from FILIPOVIC: warm milk, immediately after milking, is placed in wooden receptacles. From two to four hours is required for the formation of the curd, which is then broken up, using a wooden stirrer with a cross-piece, into pieces the size of a hazel-nut. The mass is turned upside down and the whey is collected with a large spoon through a canvas cloth placed over the whole; this process lasts from one and a half to two hours. The mass of cheese is then taken out, placed in a cloth, laid on a table, and pressed, using the lid of a vessel and a lever. Large stones are then laid on the lid so as to drain the curd completely. This process requires from one to one and a half hours. The mass is then cut into pieces of about 250 g., and these are placed in baskets and plunged into water at 65° C, the whole being turned about in the water. When the curd can be drawn out into long filaments, the treatment is complete. The mass is then placed in the moulds, where it remains for 12 hours without being pressed; the cheese is then taken out of the moulds and salted for 12 days, and finally placed to dry on racks or shelves. Pasteurisation of the curd is a feature of this process. *Kachkaval* is exported to Greece, Egypt, Turkey and other parts of the Levant.

Another important type of cheese is the *Trappist*, originally made at the convent of "Etoile Marie" in the Banja Luka, by the Trappist monks. This cheese, which has a world reputation, is very like the French Port-Salut. According to A. Törs, the Trappists do not make exclusive use of cows' milk in the manufacture, but add sheep's milk and possibly also goats' milk. As compared with the Port-Salut product, a higher yield is obtained in the case of the Trappist. According to WINKLER, the milk is curdled at 28° for 60 to 90 minutes, and the curd is warmed again from 35° to 42° C. A light pressing only is given and a soft delicate product obtained. The cheeses weigh about 1 kg.; they are placed in the ripening cellar and rubbed from time to time with a cloth soaked in hot salt water.

**Trafnik Cheese.** — This cheese is prepared mainly in the western and northern part of Novibasar, and also in the highlands of the Vlasnik-Planina (to the north of Trafnik in Bosnia). The milk of Wallachian sheep is mainly used, and the cheese shapes weighing 25 to 63 kg. are placed in casks of the form of a truncated cone on a narrow base. In Bosnia and in Herzegovina this cheese is in great demand; 100 kg. of sheep's milk yields from 18 to 21 kg. of cheese, and during the full lactation period, even more.

**Sheepskin cheese.** — This cheese is made along the Adriatic coast. The milk is warmed in a cauldron at about 30°C; it curdles in half an hour; the curd is sliced using a wooden spatula, and is stirred for 30 minutes. It is again warmed, the whey is collected and it is warmed again. Warming and filtering go on for an hour. The mass is then taken out and left for one to three days. It is then cut into pieces of about 100 g., salted and placed in a sheepskin. This cheese, when it is prepared hygienically and with full milk, has a very pleasant taste and the smell of the sheepskin is not perceptible.

**Somborer cheese.** — The milk is curdled at 30 to 35° for a fairly long time. The curd is crumbled, put into cloths and pressed. It is then sliced into pieces and placed in casks which are filled to overflowing. The containers, which are narrower at the base, hold from 10 to 15 kg. The ripening lasts from 2 to 3 weeks.

**Croatian smoked cheese.** — This is prepared from fresh milk still warm or lightly warmed with a little of the curd from the previous cheese making. The whey has to be green before the curd is taken away to be pressed. The cheese is placed in small basins and again pressed by hand; it is then left for half a day. The smoking is continued for from 4 to 8 days, thus ensuring external disinfection and good keeping quality. Each cheese weighs from 350 to 700 g. This type is mainly produced in Croatia.

**Skorup cheese.** — This is a soft cheese, somewhat oily, obtained from cows' milk. It is mainly prepared in Montenegro. The milk is warmed, and the cream allowed to rise for 24-28 hours. The cream is collected, salted and placed in a hermetically closed receptacle. This cheese is half solid, containing much cream, and has an average content of 25 per cent. water and of 62 per cent. fat.

**Manur cheese.** — This is a fatty cheese prepared with sheep's milk, sometimes also with cows' milk. It has the appearance of a clod, cleft down the middle.

**Sir mostny or Presukasa.** — This is a cream cheese having a diameter of 40 cm. by 2 to 3 cm. in height.

**Sir posny or Twdr sir and Mrsay sir.** — A hard skim milk cheese, made from sheep's milk. The cheeses are from 20 to 25 cm. across and from 4 to 5 cm. thick; the weight is 1.75 kg. Prepared in old Serbia and Montenegro.

**Macedonian cheeses.** — *Mintzitra*, a fresh cheese, soft, made with sheep's and goats' milk; the *ftinoporino* also prepared with sheep's and goats' milk, and much resembling the *brynza*; the *zadila*; the *qacheq*.

In the manufacture of cheeses in Yugoslavia, vegetable rennets are much used. Eight factories are engaged in preparing these rennets, from turnip and from *Calamus*.

The consumption of cheese in the country is comparatively small, as it is regarded among the less well-to-do classes as luxury food.

The cheese exported is almost entirely kaschkaval, the export reaching about 2,000 m. tons per year. It is much in demand in Greece, Egypt and Turkey.

#### V. — Other products.

As the introduction of modern technique and organisation into the Yugoslav dairying industry has only just begun, there are no factories of milk powder, casein, etc.

Some production of dried milk has however been initiated at Staro Petroselo.

## MISCELLANEOUS INFORMATION

TABLE GRAPE AND RAISIN PRODUCTION IN CYPRUS. — The world production of table grapes and raisins has increased considerably during the last few years, the principal countries producing and exporting table grapes being Spain, Bulgaria, Italy, Algeria and Greece. The last-mentioned country comes first in the production and export of raisins, followed by the United States, Australia and Turkey.

Cultivation of table grape varieties on a commercial scale is of fairly recent date in Cyprus, as until 1929 there were only a few small vineyards at Pitsilia and Stavrounoui. Since then, however, some quite extensive plantations have been started in the Famagosta and Limassol districts. The following are the varieties most widely cultivated:

The *Alexandria Muscat* is much appreciated because it is very productive and proves extremely resistant to wind and great heat, even without irrigation. This variety thrives on all soil-types and in every part of the island. It is subject to shedding but this defect is less marked in Cyprus (especially in the vine-growing areas of the island), than in other places. Ripening takes place during the latter half of August (early variety) and extends into September according to the altitude and locality of the vineyards. The grape stands shipment without evil effects and is a favourite on the British and Scandinavian markets. This variety is subject to attacks of *oidium*.

The *Rozaki* is a mid-season variety (late September) with satisfactory heat-resistant qualities, especially when it is not irrigated. Its beautifully formed clusters and large oval grapes make it a great favourite and it is considered one of the best export varieties; it is much appreciated on the English market.

The *Fraoula* mid-season variety, introduced from Greece, grows in deep, fertile soil and gives an abundant crop. The fruit grows in fine clusters with large oval grapes, but is unsuited for shipment to distant markets. This prevents it from becoming a favourite, but vine-growers use it for supplying the island markets and those in neighbouring countries (Egypt, etc.).

The *Sideritis*, introduced from Greece, is a late variety which does not ripen until November. Its growth is not very vigorous. This variety requires deep soil and may be irrigated. The clusters and grapes are medium in size. These grapes can stand long shipment and are fairly popular on the English market.

The *Sultana* variety, a native of Asia Minor, is characterized by its seedless grapes; it is very productive and thriving in deep, fertile soil. The grape is either small or medium-sized.

During the past ten years several other very interesting varieties have been introduced, including the Pearl of Csaba, imported from Hungary; this is a very early variety which ripens at the beginning of July; the bunches and grapes are medium in size and stand shipment to distant ports. The *Hamburg muscat* is one of the best and most delicious of the red muscat grapes but is not very productive and is not suitable for long shipment. The *Himoniatiiko* variety is sometimes found in Cyprus, ripening late (in December at Saitta) and serving the Christmas market.

Most of the types of soil in Cyprus are suited to the cultivation of the several varieties of table grapes and raisins, vineyards being found almost everywhere throughout the island. It is expected that this crop will become increasingly important during the next few years.

MOJASSES-MANURING IN THE NETHERLANDS INDIES \*. — A great number of tests were carried out with molasses-manuring on all the cane estates in Java and the results obtained are given in a bulletin (1932) of the Pasuruan Sugarcane Experiment Station, Java. Not all these tests may be considered as conclusive, but a high percentage of them correspond to the mathematical exigencies of field tests. The mean error has always been calculated and the tests are divided into three categories; (1) tests where the favourable or unfavourable difference is thrice M; (2) where it is twice M; (3) where it is  $\frac{1}{3}$  of M. Four hundred and thirty-two tests were worked out in this way, some over a series of years, the number of observations made totalling 769. The general conclusion arrived at is that molasses can be economically utilized as a fertilizer.

When applied *before* planting, molasses gives excellent results with rice. This is especially true in western Java. The effect lasts for more than one crop year; sugarcane — coming after rice in rotation — also shows an increment in yield even though no molasses is applied. This long-term effect is also noted on sugarcane, planted in the third year, after rice-sugarcane. There are indications that this effect is independent of the actual amount applied.

No significant difference was found when the molasses was applied to soils with hardpan formation. Sandy and heavy clay soils gave 73 and 49 per cent. favorable and 3 and 23 per cent. unfavourable results respectively. Best results were obtained on sandy soils in the Principalities of Djokja and Solo and in the Modjokerto district, less remarkable results on light clayey soils in Koedoes, Djckja and Solo, and on the heavy clayey soils in Cheribon, and the lowest percentage of still less remarkable — but favourable enough — results was obtained on heavy clayey soils in Modjokerto.

It is worthy of note that the effect of molasses-manuring, broadly speaking, was pronounced on soils with an insufficient water supply. Molasses is said to increase the moisture retention capacity of the soil.

*Boniteit* is defined as the potential capacity of the soil to produce sugarcane when a "normal" dose of ammonium sulphate is applied to the soil. This capacity is inversely correlated with the degree of favourable effect of the molasses on yield of sugarcane. This may explain why molasses gives better results on sandy than on clayey soils; the sandy soils selected for tests had a lower potential production capacity than the clayey soils.

Although the chances of increment in cane production increase with decreasing potential production capacity of the soil, the sugar percentage actually diminishes with soils having the characteristic values for this capacity. For example, the decrease in yield of sugar is 0.26 per cent. for sandy soils, 0.13 per cent. for light clayey soils, and 0.04 per cent. for heavy clayey soils. The decrease in sugar percentage was noted in 70 per cent. of the observations on light soils and in 56 per cent. on heavy soils. This decrease varies, however, with the dose applied and method of application. If applied at the rate of "one tin per furrow", (1) the average decrease is 0.36 per cent., at the rate of "two tins per furrow", it is 0.49 per cent. Further if applied *before* planting, it is 0.32 per cent., and *after* planting, 0.38 per cent. In the first case, it should be applied preferably in the furrows and in the latter, probably on the ridges.

---

\* BOOBERG, G., Samenvattende bewerking van de resultanten der proefvelde bij de rietcultuur op Java, 31ste Bijdraghe: Melassebemesting. *Archief voor de Suiker industrie in Nederlandsch-Indië* 1932, Deel III, No. 4, blz. 193-318.

(1) 1 tin = 17 litres (1000 furrows in a hectare, i. e., 2.471 acres).

To sum up: molasses gives better results than any of the second rate manures. Some soils respond better to molasses-manuring than others. In the former case, much higher results can be obtained with molasses than with an extra dose of ammonium sulphate or liberal doses of phosphates and potash. On light soils molasses is definitely preferable to farmyard manure, ashes or filter-mud, and if applied *before* planting may give better results than even green manuring. The following methods of economic application of molasses are recommended: (1) Apply molasses, diluted with irrigation water, in doses corresponding to "one tin per furrow" *before* or *after* rice, but in either case three months before planting. (2) Apply undiluted molasses at the rate of "1-2 tins per furrow" three weeks *before* planting. (3) If molasses is applied after planting it should be used, undiluted, on the ridges, or, diluted with irrigation water (1 per cent.), in the furrows. Lastly, molasses stocked for a year sometimes gives better results than fresh molasses.

W. B. and G. T. K.

ITALIAN NATIONAL CONGRESS ON THE HORSE, THE ROAD AND THE VEHICLE. — Under the above title a National Italian Congress was held in Verona on March 12 and 13 last, for the purpose of studying the rational utilization of the horse.

The subjects discussed were as follows: comparative cost of animal and mechanical traction; types of paving suited to roads used for animal traction; rational construction of vehicles; rational construction of wheels and material to be used for tyres; harness; shoeing of horses.

It was decided to compile a book of the proceedings of the Congress and to communicate the principal conclusions to the International Congress of Animal Husbandry to be held shortly in Zurich.

E. M.

## BOOK NOTICES \*

MONTALENTI Giuseppe, *Elementi di Genetica*. Licinio Cappelli, Bologna, 1939. 453 pp., 122 illustrations.

The study of genetics is of extreme importance at the present time; as the basis of all that concerns plant improvement, stock selection, racial studies, eugenics, etc., it plays an outstanding part in the solution of the most important and difficult problems now being discussed throughout the world.

It may be stated without exaggeration that of all the biological sciences, genetics has made the greatest progress during the present century. After the period of early gropings in past centuries, the science of genetics began to take shape with the evolutionary theories of the 19th century. It was not until after 1900, however, that, following the rediscovery of the Mendelian theory, genetics ceased to be a mere branch of botany and zoology and became a separate science, which has developed

---

\* Under this heading are included short synopses of books received for review.

with great rapidity and covers an increasingly wide range of study. New methods are discovered from day to day and new problems opened up.

This development in scope and profundity has led to the need for a scientific and complete work dealing in summarized form with the various questions as a whole and serving as a guide to the subject in general.

This work will consequently be well received, particularly as no similar study existed in the Italian language.

Zoology being the branch of study in which the A. specializes, this subject is naturally dealt with at greatest length; this gives uniformity to the work as the whole subject is studied from a characteristic point of view. Accordingly, most of the examples and illustrations are drawn from zoology and those interested in animal husbandry will find in the book much that they will appreciate.

The book is divided into 8 parts: Biological Basis and the Historical Development of Genetics - Variability - Mendelism - The Theory of Chromosomes - Mutations - Sex - Phenogenetics (manifestations of genes) - Practical Application of Genetics.

The chapter dealing with chromosomes is the most comprehensive, much space being devoted to a description of the experiments and work carried out by Morgan and his school.

The chapter on "Sex" is perhaps the most interesting, however. The A. describes his personal studies which have already formed the subject of an article in the XXXth volume of the *Enciclopedia Italiana*. The theories of sex determination are especially well developed and discussed. The same may be said for the question of intersexuality and secondary sexual characteristics. The part played by chromosomes in sex determination is discussed at length and it is to be hoped that the Author's opinions on this subject, founded on research and statistics, may be studied and assimilated by those practical farmers who have somewhat fantastic ideas in this connection. From the farmer's point of view, the most interesting is the last chapter, dealing mainly with the practical application of genetics. The reader will also find an excellent description of blood groups, the transmission of a tendency to cancer, eugenics, etc., as well as general views on the highly practical utility of genetics in every branch of life.

N. G.

BENVEGNIN L. *Les bases d'une cidrification rationnelle*. Lausanne, 1938, 39 pp.

The intention of the A., who is head of the Chemical and Bacteriological Division of the Federal Station of Experimental Viticulture and Arboriculture at Lausanne, is to provide farmers with a handy guide to cider-making. He has used the works of several authors as well as his own observations with considerable success in compiling this little book. He gives farmers clear instructions on all the essential elements for the preparation of this health-giving and pleasant drink.

The first part of this manual describes the preparation and storing of the material which is of such importance in the manufacture of a good cider, while the second part deals with gathering the apples and treating the fruit and must, as well as the way to keep the cider when made.

The small farmer will find in this little book a short but very clear and exact description of the various phases of cider making.

A. P.

VAGELER, P. *Grundriss der tropischen und subtropischen Bodenkunde*. — Zweite Auflage, Berlin, 1938. Verlagsgesellschaft für Ackerbau. 252 pp. 28 einfarbige Tafeln, 2 farbige Bodenprofile.

The A. of this excellent manual on tropical and subtropical pedology has devoted much care to the preparation of the second edition which appeared in 1938. His present work as head of the Soil Section of the Agronomic Institute at Campinas in the State of Sao Paulo, has enabled him to make extensive studies of soils in Brazil and also to put the many valuable Brazilian publications on this subject within the reach of European readers who either did not know of them or were unable to consult them owing to the language difficulty. Dr. Vageler's work is founded on long experience acquired in Africa, the Netherlands Indies and Brazil.

The basic ideas are the same as those presented in the first edition; recent observations made in Brazil have in no way altered the theories already expounded, but have enabled him to make an even closer study of important questions.

Mention should be made of the 17 new plates published in the present edition showing the action of various agents (water, wind, fire, etc.), on the soil and of the selection of interesting photographs of characteristic parts of Brazil.

### CITRUS IN THE UNITED STATES

**SUMMARY:**— 1. Introduction; 2. Present state of cultivation; 3. Varieties and stocks; 4. Experiment stations; 5. Picking and handling; 6. Packing and transport; 7. Trade; 8. Canning and by-products; 9. Conclusions; 10. Bibliography.

#### Introduction.

Fruit growing and horticulture developed greatly towards the end of last century, under the favourable conditions of temperature and moisture and following the economic development of the country, especially the great extension of railways and other means of rapid transport to all the main centres. Since the beginning of the present century, fruit growing has become very important and at present the United States is one of the largest producers in the world, particularly of apples, citrus and pears, in that order.

The orange-tree was introduced into the United States by Spanish explorers about the beginning of the XVIIth century and was first cultivated in Florida (San Agostina); later it reached California, introduced at the end of the XVIIIth century by Spanish missions at San Diego, San Gabriel, etc. These missions also introduced the olive-tree, fig-tree and other fruit trees. Recently, orange cultivation has spread to other States, particularly Texas. In 1835, a severe frost destroyed a part of the small orchards of orange trees at San Agostina. In California the first orange orchards were planted in 1841 at Los Angeles with trees from the Mission of San Gabriel, but only from 1870 on were oranges grown commercially, in the neighbourhood of the present town of Riverside. Since then the extension of orchards has been continuous.

#### Present State of Cultivation.

In view of the special climatic requirements of citrus cultivation, production on a commercial scale is limited to the south of the United States, principally Florida, California, Texas and Arizona. In recent years, production on a small scale has also been undertaken in Alabama, Louisiana and Mississippi. At present Florida and California between them produce 97 per cent. of the oranges in the United States, while Florida and Texas produce 85 per cent. of the grapefruit. The principal centre of production of lemons is in California and of tangerines in Florida. The other varieties of citrus (bitter orange, bergamot orange, lime and citron) are very little grown in the United States.

According to the latest available statistics, the total area of citrus orchards in the four largest producing states (Florida, California, Texas and Arizona) is 705,000 acres, of which 473,000 consist of orange orchards, 200,000 of grapefruit and 32,000 acres (about half each) of tangerines and lemons.

Citrus is the main agricultural industry of Florida. Citrus cultivation has developed there with extraordinary rapidity since the War. Up to 1894, the annual production of oranges averaged 4 million boxes per year, but the frosts of 1894, 1895 and 1899 so reduced the crop that the average annual production of the period 1895-96 to 1901-02 fell to only 400,000 boxes. From 1902 production began to rise again and in the period 1910-1918 averaged 7,300,000 boxes. From 1918 on the increase in production has been very great. The average crop in 1920-1930 was 16,400,000 boxes, and in 1930-1937 18,600,000. The 1937-38 oranges crop was 24,400,000.

In Florida citrus cultivation is at present mainly in the centre of the State. Most of the orchards planted in the north (1885-1899) were abandoned at the beginning of the century owing to frosts.

Orange production is the principal citrus production in Florida. Of a total of 63,000 farms, 22 per cent. of which are run by negroes, in 25,000 the principal crop is oranges, in 16,000 grapefruit and in 3,400 tangerines and lemons.

Nevertheless, generally speaking, the same farm grows all three varieties of citrus either alone or in association with other fruit or horticultural crops. The value of orange production in Florida averages 63 per cent. of the total citrus production, that of grapefruit production 30 per cent. and tangerines the remaining 7 per cent. Eighty per cent. of the citrus orchards are run by the owners, the remainder being directed by managers or leased out. The value of all citrus production (oranges, grapefruit and tangerines) in Florida is nearly 50 per cent. of the annual agricultural revenue of the State.

California produces 60 per cent. of the oranges in the United States. The production of *navel* oranges has remained constant or even tended to increase. Of a total of 148,000 farms in California, 42,000 are devoted to citrus only or citrus and associated crops, and of these 58 per cent. consist mainly of orange orchards, 28 per cent. mainly lemons and 14 per cent. mainly of grapefruit. While in California only a little over a quarter of agricultural holdings are citrus growing, in Florida the proportion is nearly three-quarters.

As has been said, Florida and California between them supply 97 per cent. (37 and 60 per cent. respectively) of the oranges of the United States, but Florida is the centre of grapefruit growing and California of lemon growing. Lemon trees are indeed grown in nearly all the citrus areas of Florida, but production is very limited and almost entirely reserved for domestic consumption, since maturation is not always sure. California contains 94 per cent. of the total lemon orchard area of the United States, and thus holds a virtual monopoly over lemons on the home market.

Grapefruit production is rather recent, being a purely post-War development. In 1914 it was still at the domestic production stage. Cultivation began in Florida but in the last 20 years has developed to a remarkable extent in Texas, where in 1919 there were only 86 acres of orchards; in 1930 there were 32,000 acres

and in 1938 91,000. The largest grapefruit centres in Texas are in the three counties of Cameron, Hidalgo and Willacy in the Rio Grande Valley.

Florida has for long been the largest grapefruit producing state. In 1921 it supplied 94 per cent. of the grapefruit of the country. But since then the proportion has steadily declined until in the 1937-38 season it was only 50 per cent. of the total. Meanwhile production in Texas, California and Arizona, particularly the first-named, increased correspondingly.

Of the 30,700,000 boxes of grapefruit produced in the United States in 1936-37, 9,630,000 came from Texas (against an average of 1,457,000 in 1928-1932) and 18,100,000 from Florida (against a similar average of 11,657,000); the remainder came from California and Arizona. In the 1937-38 season, of a total crop of 28.5 million boxes, 13 million were produced in Florida and 11 million in Texas. In the last few years there has also been a very marked development of orange growing in Texas, where suitable soils are available.

Of the 34,638,000 orange trees of all kinds cultivated in California, Florida, Texas and Arizona, 45 per cent. are not yet in full bearing, being from 5 to 15 years of age. The total number is divided as follows: 19,741,000 in California, 13,135,000 in Florida, and approximately 2 million in Texas and Arizona together.

Of the total orange trees under cultivation, 9,040,000 or 26 per cent. are from 5 to 10 years old. In this group 4,402,000 are in California, 3,271,000 in Florida, 917,000 in Texas and 450,000 in Arizona.

The number of trees from 11 to 15 years old is 3,690,000, or 19 per cent. of the total, divided as follows: 3,289,000 in Florida, 2,881,000 in California, 492,000 in Texas, and 28,000 in Arizona.

The number of trees from 16 to 20 years old is 5,696,000, or 17 per cent., and those 21 years old or over 13,212,000, or 38 per cent. of the total of 34,638,000.

In recent years, preference has been shown for planting late varieties (Valencia) rather than early varieties. The total number of late varieties of orange trees (Valencia, etc. summer oranges) in the United States is 18,411,000, 51 per cent. of which, being aged from 5 to 15 years, are not yet in full bearing. Almost two-thirds of these trees are in California and one-third in Florida. The total number of early varieties (navel etc. winter varieties) is 16,227,000, of which 39 per cent. are from 5 to 15 years old and not yet in full bearing.

The total number of grapefruit trees in the four producing states (Florida, Texas, California and Arizona) is 12,777,000, of which 69 per cent. are from 5 to 15 years old and not yet in full bearing. Only 31 per cent. of grapefruit trees are 16 years old and over and therefore in full bearing. Over half of the trees are only 5 to 10 years old and consequently an increase in production may be looked for. Most of these young trees are in Texas; for every tree that Florida has in this age-group, Texas has 3  $\frac{1}{2}$ . In California and Arizona also there are more trees of 5-10 years old than in Florida. The number of trees from 11-15 years old is about equal in Florida and Texas. Of the grapefruit trees grown in the United States 69 per cent. are late varieties.

The tangerine tree is hardly grown except in Florida, where there are 2 million trees (principally in Polk and Orange counties). Since 1930 the production of tangerines in Florida has nearly tripled, rising from 8,000,000 to 23,000,000

boxes. Briefly, the large proportion of young citrus trees in orchards promises a further increase in production in the next five years. The largest increase will be for grapefruit, particularly late varieties, a characteristic feature of grapefruit cultivation being the large proportion of newly planted and young trees not yet in full bearing. The greatest number of young trees is in Texas, which approaches the total number of trees growing in Florida. The production of oranges will also increase in the next five years, a quarter of the trees being under 11 years old and consequently not yet in full bearing. It may be estimated that the production of oranges will be stabilized at an average of about 60-65 million boxes a year, against 53 millions in 1931-32 to 1936-37. The largest increase will be for late varieties (Valencia), while the production of Navel oranges and other early varieties will not increase to any great extent in the next few years.

The citrus industry is an important item in the country's agricultural income. For example the value of oranges and grapefruit in the period 1925-26 to 1929-30 averaged 135.5 million dollars against 92.2 million in 1930-31 to 1933-1934. The fall was due to the low prices of the fruit in the 1932-33 season. From 1934-35 the value rose and in the last five years averaged 115.6 million dollars, 92.3 million of which was for oranges.

On the whole, holdings are smaller in California than in Florida. In the former state, 75 per cent. of farmers have an area of between 3 and 100 acres, while in Florida holdings of under 20 acres are rare. The agricultural population of Florida is 18 per cent. of the total population of the state, and in California only 10 per cent.

Land is more expensive in Florida than in California, but labour is cheaper. Two-fifths of the population of Florida is negro, who are employed especially for manual labour. Wages for this labour are about 30 per cent. lower than those for whites. In California wages are higher, and for certain workers in orange groves yellow labour is employed.

The annual rainfall in Florida averages 50 inches. Although the rain is well distributed over the year, there is a period of drought from March to mid-June, during which it is necessary to irrigate orchards. The Florida peninsula is a flat, sandy and marshy region with various types of soil (sandy, mixed sand and clay, slimy, etc.). The best orchards have been planted on hillsides. The most important factor in citrus growing in this region is conservation of the fertility of the soil. A large proportion of soils are very sandy or even pure sand. They lack nitrogen, phosphorus and potash, and the general practice of farmers is to employ complete chemical as well as organic fertilizers. Grapefruit trees require more fertilizers than orange-trees, and tangerine trees more than either.

### Varieties and Stocks.

Almost all the Californian orange trees are based on two varieties, the Navel and the Valencia. For Florida, Hume cites more than 50 cultivated varieties, but the most common are: Parson Brow (early), Pineapple and Enterprise seed-

less (mid-season) and Valencia (late). The Washington Navel Variety, of which 50 per cent. of Californian orange groves consist, is not very widely cultivated in Florida, since weather conditions do not make it sufficiently productive. This fact is beneficial for the development of citrus growing in the United States, since it has avoided competition between the two largest orange-producing areas.

As stocks for orange-tree grafting the following are used: *C. aurantium* L., *C. limonium* R., *C. vulgaris* R., (*C. bigaradia* D., *C. bigaradia* G., *C. bigaradia coronata*) and *C. decumana*. For tangerine trees *C. trifoliata* is used.

The following table shows the adaptability of the three stocks to conditions in Florida, according to experiments made in several parts of the state. Index 3 denotes perfect adaptability, 2 medium response, and 1 the least satisfactory response.

	Wild lemon tree	Grape-fruit tree	Bitter orange tree
1. - Rapidity of growth . . . . .	1	2	3
2. - Composition and quality of fruit . . . . .	3	2	1
3. - Fertility . . . . .	1	3	2
4. - Conservability . . . . .	3	2	1
5. - Resistance to cold . . . . .	3	2	1
6. - Resistance to base rot . . . . .	3	2	1
7. - Resistance to disease of top . . . . .	3	2	1
8. - Adaptability to acid and light soils . . . . .	1	2	3
9. - Adaptability to "heavy hummocks" and to soils with clayey sub-soil . . . . .	3	2	1

Although the grapefruit tree has, on the average, the advantage over the others, it is far from being the most acclimatized, since in the very important conditions Nos. 2, 5, 6 and 7 the wild lemon tree is most successful.

### Experiment Stations.

Experiments with citrus are carried out on various citrus Stations and also by the Associations or Co-operatives of citrus growers.

In California the Citrus Experiment Station at Riverside undertakes all kinds of direct and indirect experimental work in regard to orange and lemon production. This station has research services for agricultural chemistry, vegetal physiology, vegetal pathology, maintenance of orchards, selection, entomology, beneficial insects etc. In addition, it has local consultation agents and publishes the results of its researches in pamphlets, circulars, press articles, etc. A summary of the work is also published in the Annual Report of the University of California at Station Berkeley.

In Florida the Citrus Experiment Station at Lake Alfred studies the selection of stocks, manuring, pruning and the combatting of pests, especially the

*Aphis Spiraecola* (citrus green-fly). The most suitable soil conditions for citrus are studied at Eustis, and fruit characteristics at the Official Laboratory at Orlando.

Experiments with citrus are also made by a large number of associations and co-operatives. The California Fruit Growers' Exchange, for example, though a private institution, possesses research services, laboratories and trial fields, directed by first-class specialists, often from the services of the Federal Ministry of Agriculture. The results of the researches in regard to varieties, combatting insect pests, etc. are printed and receive a very wide publicity.

Finally, several reviews are devoted to citrus cultivation and the industry. Among them may be mention The California Citrograph, a monthly publication, edited at Los Angeles, which gives a mass of technical and economic information on all citrus problems.

### Picking and Handling.

Picking is very a important operation and demands great care. It must be carried out by skilled workers, for the fruit must not be allowed to fall and must not be handled roughly, if it is to be spoilt as little as possible. If the fruit falls, even from near the ground, it must not be packed. For picking the harvesters use baskets or sacks which they carry on their shoulders. Generally speaking, baskets are used for fruit on the lower branches, which can be reached by hand without a ladder, and sacks for the higher branches. These sacks, of sail-cloth and containing a half-box, are open at the top and have a flat bottom closed by clasps, by means of which they can be emptied easily. The best types of sacks are made so as to increase or reduce their depth by raising or lowering the bottom.

The state of maturity of an orange, which hardly changes after it has been picked, is determined by the proportion of soluble substances contained in the juice. This proportion is calculated by the aerometer. The laws of Florida and California require that oranges marketed should not contain more than one part of acid, expressed in citric acid, per 8 parts of soluble substances. For grapefruit the proportion is rather higher, since this fruit is naturally richer in acid. For lemons, size is the factor taken into consideration; the minimum size for summer picking is 2  $\frac{1}{4}$  inches diameter and for winter picking 2  $\frac{1}{2}$  inches with certain allowances. A lemon picker carries a ring, which he uses from time to time to check fruit.

The fruit must be cut with great care exactly on the peduncle without this forming a projection which could prick other fruit during manipulation. The type of clippers preferred in Florida for this operation is the short curved "tuttle". It should be noted that in wet weather the skin of the orange bruises and tears more easily than in dry weather.

The evolution of the present methods of preparing the fruit for the market is undoubtedly the most interesting part of the history of citrus cultivation. In the past the fruit was despatched in boxes, barrels and baskets of different sorts and sizes and, although on the whole it was of good quality, owing to the defect-

ive systems of handling it often arrived at the market in poor condition. The type of packing at present in use in Florida for citrus was started by Mr. E. Bean and the success of his system has caused it to be adopted in nearly all the other fruit-growing areas of the United States. The boxes used for harvesting have a slightly larger capacity than those used for picking. The ordinary dimensions are 12 inches wide, 28 inches long and 13 inches deep, with or without central divisions. These boxes must always be in good condition, must not have sharp or too fine edges, nails or splinters, and must be closely examined before use. For transporting the fruit from the harvesting ground to the packing station low carts with springs were formerly used. They are still used on a small scale, but trucks have now replaced these carts almost everywhere. When the fruit has been picked, it must not be exposed to the sun, nor may the boxes to be used for packing. The conservation of citrus fruit depends on the care taken in handling. The slightest scratch may mean the development of mould germs.

### Packing and Transport.

The handling of citrus in California and Florida has been radically transformed in the last ten years. The small local packing stations have completely disappeared, giving place to large well-equipped central houses for both packing and despatch. Uniformity has also been achieved in handling, picking, and in the product destined for the consumer's market. These houses have normally three floors. On the first the fruit is received and washed and there is a store of packing material (boxes, paper, etc.); on the second, where the offices are situated, the fruit is graded by size and quality, the boxes are wrapped up, sealed, and marked; on the third the fruit is stored and the boxes are manufactured. These houses must be centrally situated, so as to receive as much fruit as possible, while lying near a railway line, to which they are connected by a special branch line.

The boxes of fruit brought to the packing station are discharged on to conveyors, which carry them to the wasroom, where they are emptied. The empty boxes are then carried back by the same conveyor. In the washing machines the fruit is passed between revolving brushes, which completely remove all impurities; then they go to the drying machine. The latter receives a current of hot air. The fruit is carried near the machine by a conveyor and leaves the other side already dry. The fruit is then carried by another conveyor to the sorter, operated by expert workers, who examine the fruit as it passes. The fruit rejected is put on one of the conveyor belts and the remainder is classed by size and quality. Each size is carried by one of the belts to the sorting machines, which separate the fruit according to the standards adopted. Fruit which is not round (lemons, limes, etc.) must be sorted visually, before or at the moment of packing. Under the regulations lemons must fill a ring of 2 ¼ inches diameter. Those which do not attain this size are put aside. First quality fruit must be firm, ripe, well formed, glossy, with a thin and unblemished skin, without insects etc.

In the United States there are various standards for citrus boxes according to the size and quality of the fruit and the way in which they are packed. The commonest dimensions are as follows:

Types	Interior dimensions (in inches)	Capacity (in cubic inches)
Florida orange boxes . . . . .	12 × 12 × 24 <sup>7</sup> / <sub>8</sub>	3,556
Florida tangerine boxes . . . . .	6 × 12 × 24	1,728
Florida lemon boxes . . . . .	10 <sup>1</sup> / <sub>2</sub> × 14 × 24	3,528
California orange boxes . . . . .	11 <sup>1</sup> / <sub>2</sub> × 11 <sup>1</sup> / <sub>2</sub> × 24	3,174
California tangerine boxes . . . . .	6 × 12 <sup>1</sup> / <sub>2</sub> × 24	1,800
California lemon boxes . . . . .	10 × 13 × 25	3,250
California Jumbo lemon boxes . . . . .	11 <sup>1</sup> / <sub>2</sub> × 13 <sup>1</sup> / <sub>2</sub> × 25	3,574
Italian lemon boxes . . . . .	10 <sup>1</sup> / <sub>2</sub> × 13 <sup>1</sup> / <sub>2</sub> × 25	3,544

Generally, the number of fruit per box is 54 to 250 in the case of oranges, according to size; for grapefruit from 14 to 96 per box; and for lemons from 105 to 250. In order that the fruit may exactly fill the box, they are sorted so that each piece of fruit will occupy the place assigned to it in a diagram. The fruit of an upper layer must not lie exactly on top of the fruit on a lower layer but as far as possible alternate with them.

The boxes must be strong and well made. In Florida they are commonly made of deal planks with galvanized iron nails. There are now in the principal citrus areas special machines for manufacturing them. For fruit packing Florida has good raw materials available, as timber is the State's principal industry. Each citrus box carries outside a ticket with the dimensions of the box in inches, the number of fruit contained and their dimensions. It must also bear the name, stamp and address both of the producer and of the packing house.

The greater part of the citrus crop of Florida is transported by railway, while the sea is the principal means of transport of the Californian crop. For railway transport, the boxes must be placed in the trucks in such a way as not to shift during transit, for on this depends the good condition of the fruit on arrival. Generally a 40 foot truck may hold 384 boxes and a 33 foot truck 360. In the latter there are ranged 6 rows of boxes across, 30 lengthwise and 2 vertically. It has at times been attempted to increase this by adding a third row vertically, but the results have not been satisfactory. Each row of boxes must be strongly held in position by lathes nailed to the ends of the boxes and to the side-walls of the trucks, to avoid shaking.

In Florida there has not, as in California, been any great developement of refrigerating plants, since the fruit is rarely stored. As soon as packed it is despatched to the marketing centres. In California, on the contrary, both the packing houses and the co-operative citrus selling agencies have refrigerating plants, where the fruit already packed is stored often for several months, and also refrigerating trucks for transport to long distances.

## Trade.

The marketing of citrus by the producer is done in various ways: 1st, sale of the standing crop to shippers or speculators at a price fixed per box or for the whole crop; 2nd, direct delivery from the producers to the commission-agents in the various towns; 3rd, disposal to the co-operative selling agencies, such as the Florida Citrus Exchange, which deals with 60 per cent. of the production of that region.

Florida supplies 35 per cent. of the oranges consumed in the United States. The greater part of the crop is sold to the great urban centres of the northeast. The citrus areas of Florida are, on the average, only about a third of the distance of the Californian areas from the great consuming centres (New York, Boston, Philadelphia, Baltimore, Washington, Detroit, Chicago, etc.).

The marketing season for oranges in Florida begins in October and continues till June; for tangerines it is rather short (November-March). California and Arizona produce oranges all the year round (navels up to May-June and Valencias from June to November). The heaviest period of production is from November to July. The marketing season for grapefruit extends from September to August, i. e. more or less throughout the year, but the high season is from October to May. The United States import annually about 600,000 boxes of grapefruit from Puerto Rico, the heaviest month being September.

The production of lemons (at present about 300,000 metric tons), which is almost entirely centred in California, normally suffices for the internal requirements of the country. Nevertheless, the United States occasionally import lemons, particularly from Italy, which supplies 70 per cent. of the world demand.

The citrus exports of the United States are comparatively limited and average 7.5 per cent. of the total production of oranges and 4 per cent. of that of lemons. The principal countries importing citrus from the United States are Canada, which takes 50 per cent. of the total exports, and the United Kingdom 25 per cent.; the remainder goes to France, Sweden, Norway, the Netherlands, Belgium; etc. Recently exports to the United Kingdom have been increasing.

## Canning and By-products.

The production and consumption of grapefruit was practically non-existent in the United States before the War, as it still is in Europe. Now production totals 30 million boxes a year, a good third of which is used in the canning industry. In Florida, of a production of 18 million boxes of grapefruit, 6.5 million are used in the canning industry, 1 million consumed locally and the remainder despatched to the northeast of the country.

The grapefruit canning industry in Texas is very recent, as is the crop itself. In fact, before 1934-35 this industry only absorbed 50 to 100,000 boxes of grapefruit a year; this rose to 606,000 in 1935-36, to 2,563,000 in 1936-37 and to 4.5 millions, or 40 per cent. of the total annual production in 1937-38. Texas supplies the great urban centres of the centre and southwest of the States.

In California and Arizona the quantity of grapefruit used in the canning industry is comparatively very small, but is increasing as production increases.

Several years ago producers spent 1.25 to 2 dollars per ton to get rid of oranges of poor quality or of waste products. Now in certain cases by-products constitute the basis or almost the sole means of disposal of the crop. The by-products of the enormous American citrus industry are used for the manufacture of orange juice, wine and vinegar, and also for stock feed. Various essential oils are obtained, also marmalade, ices, citric acid, lime citrate, lemon vinegar citric pectine, concentrated juices, etc.

### Conclusion.

The development of citrus growing in the United States has been continuous since the beginning of this century, but has been particularly marked since the War. In view of the large number of young trees in the country, in the next few years there will be a natural increase in production, which should be stabilized at about 65 million boxes of oranges a year and 40 million boxes of grapefruit. This industry will still be able to prosper, owing to the excellent conditions in the areas of cultivation, the good co-operative systems organized for harvesting and marketing and the commercial methods adopted. At present citrus growing in the United States has become a commercialized and specialized crop, and has reached a high degree of perfection. But the natural increase of production will create two important problems: the intensification of the internal consumption of citrus fruit, the market for which is far from being saturated, and the search for new markets abroad, as well as an improved utilization of by-products.

As regards foreign markets, the United States may before long find itself in competition with the citrus regions of Central and South America, the production of which is also steadily increasing.

## THE EXTENT AND ECONOMIC IMPORTANCE OF BOVINE TUBERCULOSIS AND CONTAGIOUS ABORTION (BRUCELLOSIS) IN BULGARIA

The economic importance of these two diseases lies in the losses suffered by cattle owners through the death or prolonged illness of the cattle attacked. Both diseases are commoner in many other European countries than in Bulgaria, where the intensification of cropping and stockbreeding, the two main resources of the inhabitants, has only recently begun. Moreover, the numbers of cattle have greatly diminished during the past few years as a result of poor fodder crops, reductions in the area of pastureland, the high cost of fodder and an increase in the slaughter of cows and young cattle. The last census of livestock (December 31, 1934), showed that Bulgaria possessed at that time 1,497,624 cattle (45,7145 cows, 1,040,479 bullocks and young cattle) and 374,977 buffaloes (219,247 males and 155,730 females).

### Tuberculosis.

In Bulgaria this disease is comparativeby rare.

There are three methods of diagnosing it: (1) by clinical examination of the living animal; (2) by examination of the slaughtered animal; (3) by tuberculin reaction. This last method, practised subcutaneously, is complicated and requires much time and work; it is consequently unsuited to mass research and attempts are being made to introduce the intradermic method. The first method is practised by Government veterinary surgeons especially on cows and female buffaloes whose milk is sold on the market; it is also adopted for cattle belonging to farms where the animals slaughtered have been found infected.

About 35,000 cattle annually are subjected to tuberculin tests. Results in 1937 showed that an average of 2.13 per cent. of animals treated were suffer-

ing from the disease. The percentage varies, however, in the several regions of the country; it was very low (0.2 per cent.) in the environs of Sofia and very high (12.1 per cent.) in the neighbourhood of Stara-Sagora. The 1938 percentages have not yet been established, as the data concerning tuberculin tests during the year have not all been received and worked out. No rise in the percentage is, however, anticipated.

In order to obtain a correct idea of the spread of bovine tuberculosis in Bulgaria during the past few years, a comparison must be made between statistics in this country and in some other European countries. In Germany, for instance, a study of animals of ascertained ages has shown that 25 per cent. of those slaughtered were infected; ZWICK and KLIMMER, however, consider that the percentage should be higher, varying from 50 to 80 per cent. According to BANG, 31 to 40 per cent. of cattle in Denmark show a positive reaction to tuberculin tests. In England, from observations made in slaughter-houses and from the results of subcutaneous tests made it was found that 30 per cent. of the cattle were infected. Similar results were obtained in France by NOCARD and LECLAINCHE.

The first studies made in Bulgaria were carried out in 1920 by DIKOFF, who found that between 0.5 and 0.6 per cent. of the cattle slaughtered were infected.

The use of subcutaneous tuberculin tests later showed that the percentage of infection was much higher among live animals, varying between 15.7 per cent. in 1928 and 6.65 per cent during the last few years. According to Prof. PAVLOFF, out of 9,541 cattle subjected to tests from 1925 to 1928, 12 per cent. gave positive results. From 1929 to 1933, 103,023 animals in all were subjected to subcutaneous tests and 3.92 per cent. were found to be infected (\*).

According to the Central Institute of Veterinary Bacteriology, the results for the four years 1934-1937 are as follows:

Year	Cattle submitted to tuberculin test	Positive reaction %
1934. . . . .	78,228	3.90
1935. . . . .	37,311	2.30
1936. . . . .	36,971	2.10
1937. . . . .	31,064	2.12

The Sofia area is much richer in milch cows than other parts of the country, the numbers being 6081 cows and 1947 female buffaloes. Subcutaneous tuberculin tests have been made yearly and animals showing a positive reaction have been slaughtered, with a consequent reduction in the percentage of infected animals during the past four years. The same cannot, however, be said for the rest of the country, where systematic studies have not been carried out on a sufficiently large scale to justify such a conclusion.

---

(\*) This total includes 11,263 female buffaloes; 1.12 per cent of which were found to be infected.

In order to identify infected cattle and protect the healthy animals, the Government veterinary surgeons apply the measures provided by law. Bovine tuberculosis is on the list of contagious diseases requiring the application of the measures provided by the law promulgated in 1924 (Article 67). Article 73 prohibits the importation of livestock or of raw animal products unless accompanied by a regular certificate of origin, ownership and condition, to be presented to the veterinary surgeon at the frontier. According to Article 79 imported cattle must be submitted to a tuberculin test. Article 81 prohibits the export of infected animals.

Articles 201, 202 and 203 describe the measures to be taken in the case of animals infected or presumed to be infected. The first of these articles orders the slaughter of all infected animals or of those showing a positive reaction to the tuberculin test. The second orders the slaughter of suspect animals at the nearest abattoir and under the supervision of a veterinary surgeon. Article 203 requires a test to be made on all cows and female buffaloes whose milk is for sale; when a case of tuberculosis is declared in a herd of selected cows, all the animals must be subjected to the test.

Only Government veterinary surgeons may make the tuberculin test.

Over and above the measures just described, the Veterinary Service prescribes that when slaughtered animals are found to be infected, all the other cattle on the farm of origin must be subjected to the test and animals showing a positive reaction must be slaughtered.

### Contagious Abortion.

This disease among cows in Bulgaria is uncommon, and positive cases of abortion definitely attributable to it are very rare.

Only incomplete information is at present available in connection with this disease. In 1924 it was observed in a State herd of selected cows near Sofia. A blood test showed 94 certain cases, but as cases of abortion in Bulgaria are extremely rare, it is not possible to establish a percentage. According to PFENNINGER, and KRUPSKI, on the other hand, 20 per cent. of the cows slaughtered in Switzerland are infected with the Bang bacillus. SCHNUBER believes that an average of 30 per cent. of the cows in Germany suffer from the disease, while TELLER and ZWICK estimate that it causes the loss of hundreds of millions of gold marks annually.

In any case, it is much less widespread in Bulgaria than elsewhere. It was introduced as a result of the importation of selected stock. The fact that the first case was not observed until 1924 explains why the 1924 law concerning the Veterinary Sanitary Service does not prescribe any special measures in connection with this disease.

Prof. ST. ANGELOFF's valuable studies on contagious abortion show that in Bulgaria the disease is localized in certain regions and is only beginning to develop.

The local veterinary surgeon must immediately be notified of the appearance of the disease.

All infected animals must be isolated and put to graze separately. They can only be sold for slaughter, and infected bulls must not be used for breeding. Farms are considered as healthy if the animals show three consecutive negative reactions to serum tests made at intervals of six months, and if the stables are carefully disinfected.

Neither live nor dead cattle may be vaccinated with the Bang bacillus in Bulgaria. Farmers are advised to have a serum test made before purchasing stock.

Only eight cases of Maltese fever have been notified in Bulgaria up to the present.

In spite of their great economic importance in agriculture and stockbreeding, these two diseases have thus not had a serious influence on milk and meat production in Bulgaria, since they have not affected cattle to the same extent as in other countries.

The annual milk production in Bulgaria is estimated at 706 million litres, 550 million being cows' milk and 156 million buffalo milk. 4,143,033 litres of the former and 3,367,302 litres of the latter were processed in 1936.

The town abattoirs delivered 21,504,409 kg. of meat in 1936, the product of the slaughter of 153,179 cattle and 47,347 buffaloes. Between 1932 and 1936 Bulgaria exported a yearly average of 10,702 cattle and buffaloes, valued at 34,434,000 levas.

It cannot be denied that the two diseases under consideration are a menace to the public health. This is true, however, to a less serious extent in Bulgaria than elsewhere, partly because the diseases are not so widespread and partly because the population does not drink raw milk. In the country districts the inhabitants only take butter with their tea occasionally, while in the towns where butter and raw milk are used, the people are not open to infection because the animals supplying these two products are constantly under official supervision. The population is therefore protected from tubercular infection.

To prevent the spread of the above diseases among cattle and to minimize the losses incurred by stockbreeders, the State Veterinary Service enforces the very strict health regulations which have been described above; the results obtained from these measures have been both economic and hygienic.

In conclusion we may mention the compensation paid by the Bulgarian Government to owners of infected animals which have had to be slaughtered; the total yearly expenditure under this head is about two million levas. From 1934 to 1938 the State spent an average of 1,861,268 levas yearly on the slaughter of 1,316 infected cows and female buffaloes.

Dr. K. IVANOFF.

*Director of the Institute of Veterinary Bacteriology,  
Sofia (Bulgaria).*

## THE ORGANIZATION AND ENCOURAGEMENT OF HORSE-BREEDING IN ROMANIA (1)

### I. — History of the Organization of Horse-breeding.

The question of the administrative organization of horse-breeding was raised by Mihail KOGĂLNICEANU, the great Romanian statesman, in a circular letter addressed to the prefects on November 16, 1861. This document set forth the principle that the State, as representing the Nation, should take active measures to improve the breeds of horses as a means of developing the wealth of the country and the national defence. The measures considered necessary for attaining this object were described — purchase of thoroughbred stallions, award of prizes for good sires, etc. — and reference was made to the dangers threatening the recently united principalities unless something were done at once to improve the nation's stock of horses.

The first national stud was organized at Reviga, Copuzu and Odaia Bărağanului in 1864, with 120 fillies from the studs at the monasteries of Caldaruşani Pasărea and Cernica (Department of Ilfov) and two Percheron stud stallions imported from France. This stud had only a brief existence, and another stud, founded in its place at Pascani (Ilfov) in 1865 with English thoroughbreds, also did not last long.

Measures taken by the Ministry of the Interior, as responsible for agricultural matters, were of little avail and after 1872 the question of the improvement of equine stock was transferred to the Ministry of War, whose action was confined to direct methods.

A law concerning breeding and the improvement of the country's stock of horses was promulgated in 1874 the War Ministry was entrusted with the application of this law in collaboration with the veterinary surgeons. The Nucet (Departement of Dâmbovița) stud was established, and transferred in 1895 to Cislău (Departement of Buzău).

In the same year the War Ministry established five stallion depots for public service, the first of the kind to be set up in Romania; these depots were located as follows: Craiova with 28 stallions; Ploesti, with 31 stallions; Bucarest with 27 stallions; Slobozia with 46 stallions and one in the Dobrudja with 10 stallions. According to breed, these 142 stallions were divided as follows:

- 44 English thoroughbreds
- 6 Arab purebreds
- 4 Anglo-Arab thoroughbreds
- 88 halfbred English and Anglo-Arab stallions.

---

(1) This article is a continuation of *The Organisation and Encouragement of Horse-Breeding*, part of which has already appeared in this *Bulletin* (July 1937, page 250, January 1938, page 12 and October 1938, page 396). It has been prepared mainly on the basis of a report issued by the Romanian Ministry of Agriculture and Crown Lands and has been revised by the Ministry.

These stallions were distributed among the cavalry regiments in spring, where they formed public service stations with 3 or 4 stallions each. During this early period about 13,000 mares were served yearly.

After 1880 the task of improving the stock of horses was transferred to the Ministry of Agriculture and Industry, which till then had been merely a department of the Ministry of Finance.

Nicolas FLEVA, Minister of Agriculture and Crown Lands, established a stallion depot at Anadolkiöi in 1899 for the purpose of improving the Dobrudja stock. At the same time 27 Anglo-Arab stallions were imported from the district of Tarbes in France. In 1904, another Minister of Agriculture, Vasile LAȘCĂR, was responsible for law concerning associations in rural communes, article 166 of which provided for the purchase of reproducers and for the establishment of communal stables for reproducers.

In 1908, the Minister of Agriculture and Crown Lands, A. CARP, in agreement with General AVERUSCU, the War Minister, had a law passed transferring the Cislău stud to the control of his own Ministry.

Later, in 1909, Prof. Al. LOCUSTEANU, Director of the Veterinary College, - who had for a long time seen that such a service was necessary - succeeded in arranging for the establishment of an Animal Husbandry Service entrusted with the breeding and improvement of domestic animals. Later, under the direction of the veterinary surgeon, Dr. MANTU, it became the Animal Husbandry Department of the Ministry of Agriculture.

The stallion depots at Grași in the department of Neamțu and at Slobozia, in the department of Țalomița, were established in 1910 and 1912 respectively.

The Grași depot had 168 stallions by 1916; those at Anadolkiöi and Slobozia 173 and 22 respectively. There were therefore in all 363 stallions, of the following breeds: English thoroughbreds, Arab purebreds, Anglo-Arabs, English halfbreds, Arab halfbreds, Percherons, etc.

The State stallion service began activities in 1900 with 8 stallions serving 55 mares; in 1915 the stock had increased to 363 stallions serving 14,638 mares.

These figures illustrate the satisfactory results of the Ministry of Agriculture's policy, the remount service being supplied exclusively with horses bred in the country.

From a report by Dr. ANGELESCU, veterinary colonel, it appears that between November 1, 1914 and September 1, 1915, 532 young horses were bred for the cavalry and 1847 for the artillery; 15 per cent. of the total of 2,379 head came from the big landowners and 85 per cent. from small landowners.

The Ministry of Agriculture had also organized livestock shows as an indirect means of intervention; the first of these were held at Jassy and Bucarest in 1863 and 1864. Later, such events became frequent throughout the country.

Excellent results were obtained from the showing of colts sired by State depot stallions; these shows were organized during the period 1912-1916.

In order to encourage the breeding of remounts, the Minister of Agriculture, A. CONSTANTINESCU, instituted a bonus of from 100 to 150 lei for every horse bred in the country for army use.

From 1916 to 1918 the war interrupted all activities for the encouragement of horse-breeding, but they were vigorously resumed at the close of hostilities.

In 1919 I. G. DUCA, Minister of Agriculture, converted the Animal Husbandry Service into a General Directorate of Animal Husbandry subdivided into two sections: the Animal Husbandry Service and the Veterinary Health Service.

There has been steady progress ever since that time. During 1919, the Anadolkiol (Constanța), Grași (Neamț), and Slobozia (Ialomița) depots, whose stock had been depleted by the war, were supplied with new stallions.

The Romanian State, as successor to the Austro-Hungarian Monarchy, purchased its share of the Radautz stud, and established the Arab and Huzule stud at Rădăuți; at that time this establishment consisted of the general Administration and the stallion depot in the town of Rădăuți, an Arab stud near the town and a stud of Huzule horses in the Lucina mountains about 105 kilometres west of the town, in the Bucovina Carpathians.

The Bonțida-Cluj stud was also established in 1919, and was run by the Governing Council of Transylvania until 1921, when it was transferred to the control of the General Directorate of Animal Husbandry at the Ministry of Agriculture and Crown Lands.

The following studs were established in 1920: 1. the Rusețu (Braila) stud and stallion depot, housed in the buildings belonging to the former Crown Lands Department, to which were added a part of the Macovei-Padina estate (Departement of Buzeu) with its premises. This stud was intended for breeding horses of the Gidran stock; 2. the stud and stallion depot at Sâmbăta de Jos (Departement of Făgăraș) housed in the buildings of the former Hungarian Fogaras stud; 3. the Homorod stallion depot (Departement of Târnava-Mare) and 4. the Brebeni stallion depot (Departement of Olt).

The Turnu Severin and Fitești stallion depots (Departement of Hotin) were created in 1921 and 1922 respectively. In the same year, the provincial Animal Husbandry Commissions were instituted, under Ministerial Decree No. 40,000, May 5, 1922.

In 1923 the stud and stallion depot at Pădureni was created for breeding horses of the large Nonius type. This stud had originally been situated at Rușețu.

Also in 1923, by Ministerial Decree No. 29,999 the Ministry approved the creation of departmental funds for animal husbandry purposes and gave the animal husbandry Commissions the right to levy special taxes called "animal husbandry taxes". The departements were thus enabled to manage their own budgets, amounting to a grand total of 60,526,444 lei and to carry out useful work in this field, building communal stables for stallions, organizing shows of livestock, purchasing stallions, establishing public service stations, etc.

In 1924, Al. CONSTANTINESCU, Minister of Agriculture, promoted a bill for the opening of an extraordinary reimbursable credit; the bill was passed and published in the *Official Gazette*, No. 67, of March 26, 1924. The appropriation of 100,000,000 lei thus granted served to given loans without interest to the Animal Husbandry Commissions for the purchase of reproducers for the communes.

In order to encourage horse-breeding on the basis of a uniform programme, the General Directorate for Animal Husbandry and Veterinary Hygiene allowed the passage of a law concerning the breeding, the improvement and the protection of the health of livestock, which was published in the *Official Gazette* No. 3 in January, 1926.

Pursuant to this law, the General Directorate of Animal Husbandry established the National Animal Husbandry Institute for the study of general problems of animal husbandry, the organization and control of breeding, the keeping of stud and herd books by the unions formed by the breeders of domestic animals, etc. After a careful and documented study of the subject, the Directorate delimited the various areas for breeding each different race of domestic animal.

Under the terms of the 1926 law, the General Directorate of Animal Husbandry also created a central animal husbandry fund obtained by a levy on totalisator receipts. This fund was utilized for the purchase of stallions required for public service.

Agricultural Chambers were also instituted in 1926, including in the sphere of activity the Animal Husbandry Commissions.

The Mangalia stud was established in 1929 by the Minister of Agriculture, C. ARGETOIANU and the Chişinau (Bessarabia) depot in 1930.

This new organization of horse-breeding in Romania and the action of the General Directorate of Animal Husbandry have made great progress possible and led to the present prosperous position.

## II. — Present State of Horse-breeding Organization.

Legislative provisions regulating horse-breeding and its encouragement are contained in the law on horse-breeding (*Official Gazette* No. 3, January 3, 1926), incorporated in the law of 1937 on the organisation and encouragement of agriculture (promulgated by Royal Decree No. 1361 of 1937 and published in the *Official Gazette*, No. 67, March 27, 1937) and in the regulations annexed to that law (promulgated by Royal Decree No. 3426, 1937 and published in the *Official Gazette*, No. 236, Octobre 12, 1937).

Under the above measures, the Ministry of Agriculture and Crown Lands is entrusted with the task of encouraging the breeding and improvement of domestic animals, supervising their health and commercializing and industrializing the breeding and production of livestock. The Directorate of Animal Husbandry and Veterinary Hygiene, attached to the above Ministry, is the body which carries out all the activities undertaken by the State and which, through its technical and supervisory organs – run by veterinary surgeons – directs and controls the nation's equine production.

The Ministry is assisted in its work by the Higher Council for Animal Husbandry, which deals with all matters connected with breeding, improvement of the various breeds, and industrialization of livestock and animal products and with the administration of the central animal husbandry fund. The law provides that both horse-breeders and the military authorities shall be duly represented on the Council.

The law on stock-breeding divides the national territory into breeding areas, for each of which the races to be bred are carefully specified; the Ministry of Agriculture and Crown Lands only encourages those breeds which it considers suitable to each region. When defining these breeding areas, account was taken both of the actual situation and of the future programme, but since these factors may alter as the result of economic evolution, these areas are not more than a convenient means of directing stockbreeding development.

### State Stallion Service and Breeding.

The most important measure for the improvement of the breed of horses consists in making State stallions available for breeding purposes. A certain number of these stallions are bred in the national studs, others are purchased from private breeders. State stallions are kept as a rule in the State depots and are sent to the service stations during the breeding season. These latter stations are of two descriptions: (1) public service stations where mares belonging to owners in the district are served for a small fee; (2) private service stations: horse-breeders owning large numbers of mares can ask for a State stallion to be placed at their disposal; the mares belonging to this owner are served first, after which (as far as possible and within a maximum fixed limit) mares belonging to other breeders are also served.

The State owns 6 national studs, where a proportion of the State stallions are bred: Rădăuți (including Lucina) where Arab stallions, halfbred Arabs and Huzule horses are bred; Bonțida, where Furioso-North Star and Nonius stallions are bred; Rușețu for Gidran stallions; Sâmbăta de Jos for breeding Lipizzaner stallions; Pădureni, where Nonius stallions are bred and Mangalia, breeding purebred and halfbred Arab stallions.

The Rușețu stud breeds donkeys as well as horses.

The purpose of the studs is to supply State depots with the best sires, to diffuse the principles of rational horse-breeding as widely as possible and to give breeders the possibility of producing a sufficient number of horses to meet the requirements of the army and agriculture. Broadly speaking, every department should have its own stallion depot, either direct or through the Animal Husbandry Section of the Chamber of Agriculture.

The Romanian Government at present owns 13 stallion depots (see list on pp. 223-225).

#### (a) *State Studs:* <sup>(1)</sup>.

1. — *The Rădăuți State Stud* produces a thoroughbred Arab horse, a halfbred Arab and a mountain horse known as the Huzule, bred at Lucina, at a distance of 105 km. from the central establishment, in the Bucovina Carpathians.

---

<sup>(1)</sup> The figures given concerning numbers of horses are the very latest available, having been supplied to the Institute by the Ministry of Agriculture and Crown Lands on May 17, 1939.

The stud estate covers an area of 2,229 hectares, 200 hectares of which are pasturage, 461 hectares natural meadows, 166 hectares artificial meadows, 723 hectares arable land and 1,400 hectares mountain pastures at Lucina.

The establishment as it stands today was installed in 1919 in the buildings belonging to the former Imperial Austrian stud <sup>(1)</sup>.

The original strength - in 1919 - of the present stud was 5 stud stallions, 30 brood mares, 30 colts and fillies belonging to the Arab stud; and 2 stud stallions and 4 Huzule mares, which formed a nucleus for reconstitution of the Lucina stud of mountain horses.

The stud is at present composed as follows: 11 stud stallions (3 Arab purebreds, 4 Arab halfbreds, and 4 Huzules);

175 brood mares (1 thoroughbred English mare, 17 purebred Arab mares, 3 Anglo-Arabs, 80 halfbred Arabs and 74 Huzules);

205 colts, 1, 2, 3 and 4 year olds (15 English thoroughbreds, 17 Arab purebreds, 94 Arab halfbreds, 93 Huzules and 1 Anglo-Arab);

164 fillies, 1, 2, 3 and 4 year olds (11 Arab purebreds, 75 Arab halfbreds, 78 Huzules).

During the first ten years after its establishment (1919-1929), the Arab stud produced 243 horses (not including losses from death and elimination); these were divided as follows: 1 stud stallion, 88 mares and 54 stallions distributed among the depots. The numbers produced by the Huzule stud during the same period were 3 stud stallions, 53 brood mares and 42 stallions distributed among the State depots.

A stallion depot for public service is also attached to the stud (see description on page 223).

Simmental cows are also bred on the stud estate (12 head) as well as Turkana sheep (877 head), Large White pigs (18 head), while 144 draft animals are kept for work at the establishment and for cultivating the land belonging to it.

2. - *The State Stud at Bonțida*, near Cluj in Transylvania, produces horses of the Nonius Anglo-Norman breed and a halfbred English horse, of the Furioso-North Star type <sup>(2)</sup>.

The estate covers an area of 2,054 hectares, comprising 748 hectares of pastureland, 403 hectares of natural meadows, 115 hectares of artificial meadows and 690 hectares of arable land.

(1) The Austrian stud was founded in 1792 with native horses and horses from Russia, the Don plateau, the Caucasus and Persia; the stallions used were sires imported from Turkey, some belonging to the Lipizza breed and a Barb. Later Arab stallions were used in this Imperial stud and uniformity of type was achieved.

Horse-breeding was organized at Lucina by the Austrian Government in 1856 when the first animals - 2 stallions and a mare - were purchased in the South Transylvanian mountains.

(2) The breeds known as Furioso-North Star and Nonius come from the Royal Hungarian stud at Mezöhegyes.

The English halfbred "Furioso" is descended from the English thoroughbred *Furioso* purchased in 1841; the English halfbred "North Star" originated in the English thoroughbred sire of that name imported from England in 1852. The breeding of the "Nonius" began when the stallion *Nonius Senior* was brought to Mezöhegyes in 1815 from the French stud at Rozières.

The stud was established in 1919 on the premises of the former Hungarian remount station and it was run by the Governing Council of Transylvania until it was transferred in 1921 to the General Directorate of Animal Husbandry attached to the Ministry of Agriculture and Crown Lands.

When founded in 1919 the stud was composed of 14 stud stallions, 156 brood mares, 104 colts and fillies (1, 2, 3 and 4 year olds), all Nonius, Gidrans and Furioso-North Stars and almost all from the Royal Hungarian stud at Mezöhegyes, *i. e.* from the original stock of these breeds.

To-day the stud comprises the following stock: 12 stud stallions (2 English thoroughbreds, 4 Furioso-North Star and 6 Nonius stallions);

102 brood mares (11 English thoroughbreds, 36 Furioso-North Star and 55 Nonius mares);

102 colts, 1, 2, 3 and 4 year olds, (9 English thoroughbreds, 44 belonging to the Furioso-North Star and 49 to Nonius stock);

125 fillies, 1, 2, 3 and 4 year-olds (6 English thoroughbreds, 51 of Furioso-North Star and 68 of Nonius stock).

During the first ten years after its establishment (1919-1929) this stud produced 2 stud stallions, 282 State stallions for the depots and 127 brood mares, without counting animals which died or were eliminated.

The establishment also runs a stallion depot for public service (see description on page 224).

Simmenthal cattle are also bred on the estate (47 head), as well as the black and white varieties of Turkana sheep (432 head), Mangalitza and Large White pigs (29 head), Rhode Island and Plymouth Rock fowls (150 head), while 117 draft animals are kept for various types of work in the establishment and on the estate.

3. - *The State Stud at Rușețu (Braila)* produces an Anglo-Arab horse known as Gidran <sup>(1)</sup>.

The estate covers an area of 2,270 hectares, 252 hectares of natural meadows, 120 hectares of artificial meadows and 1,878 of cultivated land.

The Rușețu stud was founded in 1920 with Nonius stock, but in 1924 this was transferred to Parța, near Timișoara and replaced by the Gidran stud from Răudăți. The stud is housed in the buildings of the old Crown estate, to which a part of the Macovei-Padina estate (Departement of Buzău) has been added with its premises. Breeding commenced with 2 stud stallions, 69 brood mares and 48 colts and fillies. The actual stock now numbers 9 stud stallions (2 half-bred Arabs, 5 Gidran and 2 American trotters);

82 brood mares (3 halfbred Arabs, 71 Gidran and 8 American trotters);

84 colts (2 Arabs, 74 Gidran and 8 American trotters);

77 fillies (2 Arabs, 70 Gidran and 5 American trotters).

---

(1) The Gidran breed — Hungarian Anglo-Arab — belonged to the Royal Hungarian stud at Mezöhegyes and originated in the Arab thoroughbred *Gidran Senior* imported from Arabia in 1815. At first only pure bred Arab stallions were used in breeding the Gidran horse, but after 1860 the stock was crossed with English thoroughbreds in order to improve the breed; since then the Gidran stock has been officially known as an Anglo-Arab breed.

During its first decade, this stud produced 3 stud stallions, 111 brood mares and 108 stallions for the depots, not including losses from death or elimination.

The establishment also breeds Poitou donkeys, of which there are 15 in the stud at present.

A stallion depot for public service is annexed to the stud (see description on page 224).

Simmenthal cows are also raised on the estate (13 head), as well as Karnabat sheep (341 head) and Mangalitza and Large White pigs; are kept 140 draft animals for work in connection with the stud and on its land.

4. - *The Sâmbăta de Jos (Făgăraş) State Stud* produces a Lipizzaner horse<sup>(1)</sup>.

The estate covers an area of 498 hectares, 64 hectares being pastureland, 37 hectares natural meadows, 109 hectares artificial meadows and 156 hectares arable land.

In 1920 the stud was installed in the buildings belonging to the former Hungarian Fogaras stud, founded by the Royal Hungarian Government in 1875 with Lipizzaner stock from the Mezöhegyes stud (where breeding of these horses commenced in 1860) and also with animals imported directly from Lipizza. The present stud began activities in 1920 with 3 stallions and 22 mares belonging to the Lipizzaner breed.

Present stock is as follows: 8 stud stallions, 84 brood mares, 84 1, 2, 3 and 4 year old colts and 99 1, 2, 3 and 4 year old fillies, all Lipizzaner.

From 1921 to 1928 the stud produced 64 brood mares and 56 State stallions distributed among the depots.

A depot for public service is annexed to the stud (see description on page 224).

Merino sheep (86 head) are also raised on the estate, as well as Large White pigs (15 head) and Rhode Island poultry (43 head) whilst 26 draft animals are kept for use on the stud and farm.

5. - *The State Stud at Pădureni* (the former Parţa Stud, near Timişoara in the Banat) produces an Anglo-Norman horse known as the Large Nonius<sup>(2)</sup>.

The estate covers an area of 1,460 hectares, comprising 159 hectares of pasture, 104 hectares of natural meadows, 139 hectares of artificial meadows and 1,218 hectares of arable land.

(1) The Lipizza breed originated at the Royal and Imperial Stud belonging to the Austrian Court at Lipizza in the Carso mountains and founded by the Archduke Charles in 1580. The initial stock consisted of Spanish stallions and Andalusian mares; later oriental blood was added to the Spanish and Neapolitan strains. Thus the Lipizza breed was the result of crossing these various strains and re-crossing them with the local horse.

(2) In the Royal Hungarian Stud at Mezöhegyes, where they originated, the Nonius horses are divided into two groups: in the first group of large animals (Large Nonius) are included the horses measuring 168 centimetres at the withers, measured with the tape; the other group comprises the smaller Nonius horses (Small Nonius). The horses in the former group are rarely more than 174 centimetres in height; in the latter group they are seldom less than 160 centimetres.

The breeding of large Nonius' was began at Rușețu in the autumn of 1919. The Pădureni stud was founded in 1923 and the stock transferred there from Rușețu. Breeding commenced with 5 stud stallions, 82 brood mares, and 49 1, 2, 3 and 4 year old colts and fillies.

Stock at present is: 4 stud stallions, 78 brood mares, 78 1, 2, 3 and 4 year old colts and 65 1, 2, 3 and 4 year old fillies, all belonging to the Nonius breed.

During the first ten years (1919-1929) the stud produced: 1 stud stallion, 99 brood mares and 121 State stallions distributed among the State depots.

A stallion depot for public service station is annexed to the stud (see description on page 224).

The establishment also breeds black Ratzka sheep (567 head), Mangalitza pigs (11 head) and owns 102 draft animals for use on the stud and farm.

6. - *The State Stud at Mangalia* produces purebred and halfbred Arabs.

The estate covers an area of 1,587 hectares, comprising 144 hectares of grazing land, 60 hectares of natural meadows, 30 hectares of artificial meadows and 1,300 hectares of arable land.

The stud was founded in 1929 when C. ARGETOIANU was Minister of Agriculture, and is an entirely new establishment. The stock was brought from the stud formerly run by the Ministry of War and installed at the Jigalia (Ialomița) remount depot. When the stud was established the stock amounted to 115 animals for breeding purposes, including 3 stud stallions.

Present stock is as follows:

purebred Arabs: 3 stud stallions, 12 mares, 15 fillies (1, 2, 3 and early olds), and 11 colts (1, 2, 3 and 4 year olds);

halfbred Arabs: 2 stud stallions, 56 brood mares, 61 fillies (1, 2, 3 and 4 year olds) and 64 colts (1, 2, 3 and 4 year olds).

The establishment also raises Karnabat sheep on the estate (120 head), and owns 107 draft animals for use on the stud and farm.

#### (b) *Stallion Depots* <sup>(1)</sup>.

There are 13 stallion depots in Romania, 5 of which are annexed to State studs:—

1. - *The Rădăuți Stallion Depot* has 111 stallions 2 English thoroughbreds, 13 Arab purebreds, 4 English halfbreds, 65 Arab halfbreds, 1 Anglo-Arab and 35 Huzules.

In 1937 service by stallions belonging to this station was as follows: 3,751 mares served at 46 public service stations, and 427 mares served at 18 private service stations, making a total of 4,178 mares served. The Rădăuți depot serves the following departements: Rădăuți, Storojineț, Cernăuți, Suceava, and Câmpu-Lung.

<sup>(1)</sup> The figures given concerning numbers of horses are the latest, having been supplied to the Institute by the Ministry of Agriculture on May 17, 1939.

2. - *The Bontida Stallion Depot* has been operating for several years in connection with the stud of the same name. The present stock comprises 117 stallions (5 English thoroughbreds, 13 English halfbreds, 1 Arab, 35 Furioso-North Star, 59 Nonius, 3 Lipizzaner and 1 Ardennais).

Service given in 1937 was as follows: 3,581 mares served (3,295 in 40 public service stations and 286 in private service stations). This depot serves the departements of Salaj, Bihor, Satu-Mare, Someş and Năsăud.

3. - *The Ruşefu Stallion Depot* has 62 stallions (2 English thoroughbreds, 1 Arab purebred, 3 English halfbreds, 3 Arab halfbreds, 1 Lipizzaner, 8 trotters, 43 Gidrans and 1 Nonius).

Service given in 1937 was as follows: 3,254 mares served (3,152 in 33 public service stations and 102 in 5 private service stations). This depot serves the departements of Braila, Râmnicul-Sarat, Covurlui, Putna, Tecuci and Tutova.

4. - *The Sâmbăta de Jos (Făgăraş) Stallion Depot* owns 74 Lipizzaner stallions. During 1937, 79 stallions belonging to this depot served 2350 mares (2097 in 48 public service stations and 253 in 10 private service stations). This depot serves the departements of Făgăraş, Alba and Sibiu.

5. - *The Pădureni Stallion Depot* now owns 191 stallions (3 English thoroughbreds, 6 Furioso-North Star, 175 Nonius, 2 thoroughbred and 5 halfbred Ardennais).

Service in 1937 was as follows: 7,750 mares served (7,571 in 66 public service stations and 179 in 5 private service stations). This depot serves the departements of Timiş and Arad.

Besides the stallion depots annexed to the studs, there are 8 others: 3 of these (Anadalkioi, Graşi and Slobozia) existed before the war, while the remainder were established after 1920.

6. - *The Anadalkioi (Constanta) Stallion Depot* has 127 stallions (15 English thoroughbreds, 7 Arab purebreds, 2 Anglo-Arab thoroughbreds, 8 English halfbreds, 90 Arab halfbreds, 1 Lipizzaner, 1 trotter, 2 Gidrans and 1 Nonius).

Service in 1937 was as follows: 5,167 mares served (4,960 in 49 public service stations and 207 in 10 private service stations). This depot serves the departements of Constanţa, Tulcea, Caliacra and Duroştor.

7. - *The Graşi Stallion Depot* has 110 stallions (4 English thoroughbreds, 1 Arab purebred, 3 Anglo-Arabs, 8 English halfbreds, 55 Arab halfbreds, 10 Huzules, 23 Gidrans, 2 Nonius and 4 Ardennais).

Service in 1937 was as follows: 4,325 mares served (3,974 in 41 public service stations, and 351 in 11 private service stations). This depot serves the departements of Botoşani, Bacău, Dorohoi, Baia, Iaşi, Neamţ, Roman, Falcu and Vaslui.

8. - *The Slobozia Stallion Depot* has 180 stallions (52 English thoroughbreds, 37 English halfbreds, 3 Arab halfbreds, 1 Huzule, 7 trotters, 46 Gidrans, 19 Nonius, 8 Ardennais, 5 Ardennais halfbreds, 1 Anglo-Arab and 1 Oldenburg).

During 1937, 8,042 mares were served from this depot (7,753 in 87 public service stations and 289 in 15 private service stations). This depot serves the departements of Ialomița, Ilfov, Vlașca, Teleorman, Argeș, Muscel, Dâmbovița and Prahova.

This stallion depot also rears two varieties of the Tzigaiia-Bucalaia breed of sheep: the black-faced and the red-faced varieties (18 stud rams and 626 ewes).

9. - *The Homorod (Târnava-Mare) Stallion Depot*, has 193 stallions (8 English thoroughbreds, 31 English halfbreds, 3 Arab halfbreds, 23 Lipizzaner, 32 Furioso-North Star, 95 Nonius and 1 Oldenburg stallions).

In 1937, 7,814 mares were served in 116 public service stations and 413 in 9 private service stations, amounting in all to 8,227 mares served. This depot serves the departements of Târnava-Mare, Târnava Mica, Turda, Făgăras, Brașov, Trei-Scaune, Odorhei, Ciuc, Mureș and Sibiu.

10. - *The Brebeni (Olt), Stallion Depot* has 85 stallions (9 English thoroughbreds, 41 English halfbreds, 3 Arabs, 1 Anglo-Arab, 3 Huzule, 4 Lipizzaner, 1 trotter, 2 Gidrans, 7 Nonius, 5 Ardennais and 9 halfbred Ardennais stallions).

During 1937, 2,213 mares were served in 67 public service stations. This depot serves the departements of Dolj, Romanați, Olt, Argeș, Teleorman, Vâlcea, Gorj and Muscel.

11. - *The Turnu-Severin Stallion Depot* has 110 stallions (6 English thoroughbreds, 16 English halfbreds, 15 Arab halfbreds, 1 Anglo-Arab, 8 Huzule, 9 Lipizzaner, 14 Furioso-North Star, and 25 Nonius as well as 3 Ardennais thoroughbreds and 1 Ardennais halfbred).

During 1937, 4,291 mares were served in 46 public service stations and 10 in one private station. This depot serves the departements of Mehedinți, Severin, Hunedoara and Arad.

12. - *The Fitești (Hotin) Stallion Depot*, has 75 stallions (1 English thoroughbred, 12 English halfbreds, 29 Arab halfbreds, 11 trotters, 15 Gidran, 5 Nonius and 2 Oldenburg stallions).

During 1937, 3,040 mares were served in 35 public service stations and 64 in 2 private service stations, a total of 3,104 mares. This depot serves the departements of Hotin, Sorocea and Bălți.

13. - *The Chișinău (Bessarabia) Stallion Depot* has 44 stallions (1 English thoroughbred, 3 English halfbreds, 39 trotters and 1 halfbred Ardennais stallion).

During 1937, 2,207 mares were served (2,153 in 37 public service stations and 54 in 7 private service stations). This depot serves the departements of Lăpușna, Orhei, Tighina, Cetatea Albă and Ismail.

#### Private Stallion Service.

Besides the public service stations there are also many private service stations served by stallions belonging to private owners. Permits must be obtained from a Commission of experts before these stallions can be used for public

service. Stallions refused a licence by the Commissions of Experts are castrated at the owner's expense if there is no other way of preventing their being used for public service.

The following table gives the numbers of State and authorized private-owned stallions utilized for service during the year 1936-37. The figures show that out of a total of 4,738 stallions used, 1,539 were State stallions from the depots, while 3,199 were authorized private-owned stallions.

*Number of stallions belonging to stallion depots and of authorized stallions utilized for service in the year 1936-37.*

Breeds	Number of Stallions		Total
	Belonging to stallion depots	Belonging to private owners and authorized for service	
English thoroughbreds . . . . .	116	14	130
Arab purebreds . . . . .	18	78	96
Anglo-Arab thoroughbreds . . . . .	6	—	6
English halfbreds . . . . .	188	423	611
Arab halfbreds . . . . .	249	196	445
Anglo-Arab halfbreds . . . . .	5	—	5
Furioso-North Star . . . . .	79	—	79
Gidran . . . . .	161	133	294
Lipizzaner . . . . .	371	419	790

Total . . . . .	1,539	3,199	4,738

### III. — Other Provisions for the Encouragement of Horse-breeding.

#### (a) State Subsidies.

To increase the numbers and improve the quality of stock, the State gives subsidies every year for horse-breeding. The principal subsidies are: (a) bonuses for the maintenance of stud stallions and brood mares; (b) bonuses for horses sold to the army (remount service); (c) subsidies for studs with a stock of at least 10 brood mares.

The maintenance bonuses and subsidies under (a) and (c) are awarded by the Ministry of Agriculture (Directorate of Animal Husbandry Services)—if the Animal Husbandry Sub-Commissions express a favourable opinion—to breeders owning

authorized stallions or good brood mares of known origin, capable of reproduction and of transmitting their good qualities to their offspring.

At the beginning of the year each Animal Husbandry Sub-Commission submits for the approval of the Ministry an estimate of the sum necessary for these subsidies.

Besides these subsidies, the State gives others to the breeding unions and awards prizes and diplomas at the shows. Horse-breeders are also assisted by the purchase at a good price of stallions exhibited at the shows.

#### (b) *Associations.*

Through the departmental Chambers of Agriculture, the Ministry of Agriculture encourages the formation of local societies and unions for horse-breeding, under a standard statute.

Under the terms of the law on cooperation, these local associations may federate by departements or by regions; they work on the lines laid down by the Chambers of Agriculture and enjoy all the advantages and rights foreseen by the law on cooperation.

Besides the local societies and unions already in existence, the heads of the horse-breeding establishments (studs and stallion depots) sometimes form other associations under the auspices of the National Animal Husbandry Institute.

Among the numerous horse-breeding associations in Romania, mention should be made of those operating in the capital: the Jockey Club – the Society for Trotting Horses – The Association of Breeders of English Thoroughbreds – The Association of Breeders of Trotters – Some of the associations operating in the provinces are for general purposes, while others have been created for the purpose of encouraging a given breed or type of horse. Others, again, encourage horse sports, and still others assist their members in the field of commerce.

#### (c) *The Stud-Book System.*

The Stud-Book of thoroughbred horses is kept by the “Jockey Club”, with headquarters at Bucarest. The Stud-Book for halfbreeds is kept by the “Society for the encouragement of the breeding of halfbreeds”, with headquarters at Braila; the Trotter Stud-Book is kept by the “National Society for Trotting Horses”.

I. M.

### **MISCELLANEOUS INFORMATION**

THE ACTION AND USE OF COLCHICINE IN THE PRODUCTION OF POLYPLOID PLANTS. — The discovery of the action of the drug colchicine on nuclear division, making it the most reliable agent yet used in the production of polyploid plants, has excited great interest even among laymen and is of importance to those working on the cytology or genetics of plants.

The Imperial Bureau of Plant Breeding and Genetics, of Cambridge, has issued a bulletin on the subject, summarizing the already fairly extensive literature. This bulletin begins by explaining the chromosome doubling; next a detailed account of the action of colchicine on mitosis and meiosis is given, followed by summaries of the results obtained from the use of colchicine for producing polyplid plants. The action and use

of acenaphthene, which Russian workers have shown to be a similar agent to colchicine, are also described. Particular attention has been paid throughout to treatments, and dosages and some recommendations are given which should be helpful to those contemplating the production of polyploids. All the literature that appeared up to the end of January 1939 is included and listed in a bibliography of 38 references.

J. L. F.

OLIVICULTURE IN LIBYA. — In a long and interesting article (*Principali aspetti dell'olivicultura libica, L'agricoltura coloniale*, Firenze, 1939, n° 4, 24 pp., tables, illustrations, bibliography), Signor Vivoli gives very complete information on the history and recent progress of oliviculture in Libya.

The olive has been grown in Libya since time immemorial; it would appear to have been introduced by the Phoenicians towards the XII or even the XIV century B. C. During the period of Roman domination the crop was already common and was one of the principal agricultural resources of the country. The Arabs destroyed a large part of the groves, as they did in Tunisia. The revival of olive cultivation in this area has been undertaken by the Italians during the past twenty years. According to Turkish statistics dating from before the Italian occupation (1909-1019), there were then some 500,000 olive trees in the country. The Italian agrarian policy has developed the native groves to a considerable degree, especially during the last few years, and today the number of trees in these groves is 800,000, an increase of 60 per cent. since 1913.

The greatest development in Libyan olive culture, however, has been due to Italian colonists, and especially during the period since 1926. At that time there were 68,000 olive trees in the European groves and the number increased to 953,000 trees in 1930, 1,342,000 in 1933 and 1,778,955 in 1937. Since 1926, Italian settlers have therefore planted an average of 170,000 olive trees per annum; when these trees reach full production it will be possible to count on an output of 5 million kg. of oil per annum.

The 1,778,955 olive trees planted by Italian settlers over an area of 61,717 hectares, as registered by the census taken on April 21, 1937, are divided up as follows: 724,818 trees planted over an area of 23,635 hectares in unmixed cultivation; 764,547 trees planted over an area of 28,383 hectares and interspersed with almond trees; 245,060 olives grown on an area of 8,188 hectares and interspersed with vines; and 53,530 olives planted on an area of 1,510 hectares and interspersed with vines and almond trees.

The two most important oil-producing centres are in the provinces of Tripoli and Misurata. More than a million olive trees are already growing on the plain skirting the Tripoli coast.

Owing to the special requirements of this crop, the Agrarian Services in Tripolitania have been obliged, in order to avoid serious mistakes, to study and solve various problems in regard to environment, propagation methods, choice of varieties, the spacing out of trees, both on unirrigated and irrigated land, catch crops, etc. The results obtained show the care with which these problems have been studied and solved. From the technical and economic standpoints, the organic system is considered the best method of propagation (cuttings, scions, stocks, etc.). In regard to the selection of varieties, although in the early days of colonisation Tuscan varieties were planted, there was later a tendency to grow some of the sturdy and productive native varieties and these have been extensively propagated. It was feared that difficulties would be encountered with the Italian varieties as a result of the different climatic conditions; these have, however, given good results so far, and time will tell whether they can adapt themselves to the climate of Tripolitania. On dry soils the trees are usually planted on the chequer system, 20 metres apart, while the distance adopted on irrigated land is from 8 to 10 metres. However, given the aridity of the areas planted to olives, which compels them

to spread their roots out in search of moisture, it is advisable to plant the trees at a distance of 25 metres.

In many groves the olive is cultivated in association with the almond and the vine. Although such crop mixtures are necessary to ensure immediate income during the early period before the olive trees begin to bear, they have their disadvantages because the oil yield is diminished when the olive trees begin to bear. At the present time the cultivation of almonds or any other trees in association with the olive is prohibited, while the vine must be uprooted around the trunk of the olive, this being practised on a wider circumference as the tree develops. Annual crops are much more suited to cultivation in alliance with the olive (fodder crops and cereals), but they should not be cultivated after the tree is full grown.

Owing to the light rains which fall in these regions and to their unsatisfactory distribution throughout the year and even from year to year, wherever possible the olive should be irrigated. The ground should be harrowed several times during the dry season in order to prevent as far as possible the evaporation of moisture from the ground.

The present yearly production of olive oil in Libya amounts to 26,000 quintals, produced almost entirely from the native groves. The total consumption is estimated at 36,000 quintals, with a consequent deficit of 10,000 quintals per annum. The olive groves planted by the Italian settlers will, however, soon be yielding a crop, and then it will be possible to count on a total production of from 65 to 85,000 quintals, half of which will be available for export.

Even now it may be anticipated that within a very few years Libya will be able to contribute towards filling the deficiency in fats from which Italy is still suffering, since, although the soil is poor, there is no doubt that oliviculture there will be successful.

A. P.

POULTRY-KEEPING IN THE NETHERLANDS. — The Netherlands have an area of 34,917 square km. and a population of 8.5 million inhabitants, the density being therefore 240 inhabitants per square km. The aggregate value of agricultural production is estimated at 700 million florins yearly, poultry accounting for more than 10 per cent. of this amount.

The development of poultry-keeping dates mainly from the beginning of the present century, but more particularly from the end of the War.

At present there are more than 28.5 million hens producing 3 billion eggs per annum, 40 per cent. of which are exported. Germany absorbs 70 per cent. of the exports, England 22 per cent. and the remainder is divided between Belgium, Switzerland and Spain.

The White Leghorn is the most popular breed, followed by the Rhode Island Red and since their introduction into the country these two breeds have been the object of continuous selection, resulting in very high production. The Barneveld, Welsum and blue breeds in the northern part of the country are the result of crossbreeding between native and imported races. The two former breeds give fine large eggs (70 grammes in weight); the last mentioned, which is a rather early layer and easily fattened, produces especially young eating chickens.

Chicken rearing, with the chief centre in the north of the country, is also a very important branch of poultry production. Exports of live chickens amount to about 1.5 million head per annum, while 1,700 tons of dead poultry are exported mostly to England, France and Germany.

Duck rearing has for long been carried on in the Netherlands, especially in the west, and is now general throughout the country. The most common breed is the Khaki Campbell. The principal aim of duck breeding is egg production.

Poultry farming is generally considered a secondary activity on farms, and there are very few specialized poultry farms, the economic results of such enterprises not having been very satisfactory as a general rule.

Instruction in poultry keeping is given by a State Service under the direction of a State Councillor for Poultry Keeping, who is also the director of the Netherlands Poultry Institute. Vice-Councillors and Assistants are also appointed in the various districts and they contribute to the improvement of the poultry keeping industry. Members of the instruction service and poultry experts give annual courses and train poultry keeping instructors. Theoretical and practical winter courses are organized in every district: the number of these courses given in the 1938-39 season was 102.

Exports of hen and duck eggs are regulated by the law of November 29, 1930: markings, standards, etc., are specified under this law, which also set up a very severe control exercised by the Beekbergen Office.

The main factors which have contributed towards the progress and improvement of poultry-keeping in the Netherlands may be summarized as follows: (1) diffusion of specialized instruction in poultry-keeping; (2) cooperative organization of producers; (3) breed selection, checking of egg-laying, etc.; (4) control of exports; (5) state intervention.

A. P.

RECENT PROGRESS IN THE CONSTRUCTION OF COMBINE-HARVESTERS. — Two new models of combine-harvesters, characteristic of present trends in the construction of these machines, have recently been put on the market.

These are the small "All-Crop Harvester", produced by the Allis-Chalmers Company in the U. S. A. and the Harvester-Thresher-Binder built by the Claas company in Germany.

The Allis-Chalmers small combine harvester is a new and smaller edition of the "All-Crop Harvester" produced three years ago, which cuts a 60 inch swath and is constructed for the medium-sized family farm in the United States (see this Review, 1936, No. 8, page 318). The new model cuts a swath of only 40 inches and is planned for the use of a small family farm of less than 100 acres. Its total weight is 1,700 lb. It is designed so that it can be drawn or operated by a single-furrow plough tractor. The price in the United States is 345 dollars.

The machine is built without a chassis, its solidity being ensured by a pressed sheet-iron framework. The various parts are arranged so that the crop traverses the machine in a straight line in an inverse direction to the progress of the harvester; the cereals, falling from the cutting bar on to a moving platform, are conveyed in a straight line to the thresher, which is of the beater type and which then throws them on to a counter-beater; the beaters of these two parts are rubber-covered as in them previous model, so that threshing is softened and the machine may therefore be used for peas and other grains as well as for cereals. The threshing drum is 3 feet in length with a diameter of 15 inches. The shaker is 5 ft. in length and 3 ft. in width; the distance between the axle of the drum and the exit for the straw is 6 ft. 3 in. The overall width of the machine is 7 ft. 1 in. and length 16 ft. 3 in. Under favourable conditions, one acre can be harvested and threshed per hour. In speaking thus of "harvesting", the grain only is meant, as the straw and husks are thrown back on the field; this simplifies the design of the harvester-thresher and saves transporting the straw, but is an obstacle to the sale of these machines in districts where the straw has to be utilized. Moreover, by leaving the husks on the ground all the weeds are also left behind and there is a risk of these invading the field again. Collection of the husks would eliminate this defect, which is common to American combine harvesters.

European farmers cannot do without the husks and straw, and this complicates the use of combine harvesters considerably. Collection of the straw by a combine harvester was accomplished in France many years ago by DOULHET with an ingenious machine (see this *Review*, 1928, No. 9), which however was mable to clip and clean the grain. New machines producing cleaned grain have been designed by W. G. BRENNER in Germany for the Claas Company. The first of these machines, of very original design, with a cutter in front and propelled by a tractor, and in which the cereals were threshed by a very short vertical beater, seems to have met with considerable difficulties in practice, as the more recent model constructed by the same firm is built on more usual lines.

In this machine, too, work proceeds in a single direction, in this case crosswise to the direction in which the thresher advances. This form of construction has had to be adopted so that the crop may reach the thresher from the side and thus permit of the straw reach the thresher from the side and thus permit of the straw being bound in bundles afterwards. In Europe it is not advisable to press the straw behind the harvester-thresher as it is still damp and would not dry satisfactorily. The transverse process requires the axle to be arranged lengthwise. In principle therefore this model is similar in design to the DOULHET combine harvester, but the thresher is arranged at a higher level and the necessary cleaning devices have been introduced into the machine. The cutting bar is a little more than 2 metres in width and the weight of the whole machine is about 2 tons. It requires a tractive force of about 38 HP. The price in Germany is about 5,000 marks.

Contrary to the system adopted in American models, cereals are cut very low, but the machine cannot operate unless the stalks are at least 1 m. 60 in height. The straws is bound in bundles which gather on a shelf opposite the cutting bar and is then dropped on the ground in groups. The husks are blown into a covered trailer which is replaced by another when full. In this the seeds of the weeds are also collected and can do no harm. If the straw is still damp it can dry on the field while the grain is put under cover. In comparison with other methods used at the present time, the harvester-thresher-binder offers the advantage of a great economy of labour. Its turnover of about 300 quintals of cleaned cereals per day makes it especially suitable for large farms. However, in Europe even more than in the United States, a need is felt for machines suited to the small family farm, and the small model of the Allis-Chalmers harvester-thresher should encourage constructors to follow up this line.

H. J. H.

CONDITIONS FOR THE USE OF OLIVE-OIL IN THE NORWEGIAN CANNING INDUSTRY. — M. Beaujard, French commercial attaché in Norway, in the "*Moniteur officiel du commerce et de industrie*" (February 23, 1939) describes as follows the conditions for the use of olive-oil in the canning of brislings and small herrings.

These conditions were drawn up by the Laboratory of the Norwegian canning industry and imposed by the Hermetikkfabrikkenes Brislingcentral A/S (Canned Brisling Marketing Board) and the Hermetikkfabrikkenes Sildcentral A/S (Canned Herring Marketing Board), i. e. the organizations controlling the export of Norwegian canned fish, and must be strictly observed by the exporters of olive-oil. They are listed below.

- (1) The oil must be clear and free of water, mucilage and other impurities, which means that it must have been carefully filtered.
- (2) It must have a golden yellow tint with a slight greenish or brownish tinge.
- (3) It must have a pure and agreeable taste and odour.
- (4) The acidity (percentage content of free fatty acid) must not exceed 1.7 per cent., if the product consists only of natural olive-oil.

- (5) Pressed oil, chemically refined, if contained in a blend, must not exceed 30 per cent. of the mixture. This refined oil must be of good quality.
- (6) It must not contain refined extraction oil from the oil cake (sulphide oil).
- (7) It must be non-precipitating, i. e. it must not precipitate solid fats at a temperature of  $+8^{\circ}$  to  $+4^{\circ}\text{C}$ .
- (8) The index of iodine must not exceed 88.
- (9) Its rancidity must not exceed 10.0 in red Lovibond units under the Kreiss quantitative analysis.
- (10) The ash content must exceed 30 milligrammes per litre of olive-oil.

#### Notes.

*Condition 1.* — That the oil should be carefully filtered and free of water and foreign bodies is important for its conservation. The water (water of the fruit extracted in pressing) and other foreign bodies increase the acidity which may gradually lower the quality of the oil.

*Condition 2.* — The colour of the olive-oil is a criterion for judging its quality. The golden yellow tint is generally accepted as an indication of good quality. If the oil has a pronounced green or brown tinge, it may indicate that the olives were not ripe (windfalls) or, as is more often the case, that the fruit has been subjected to too strong pressure, so that the chlorophyll has mixed with the oil; after a certain period of storage the marked green tint of certain newly manufactured natural oils generally becomes yellow brown.

*Condition 3.* — If the oil has a disagreeable or unnatural taste or odour, it means that rotten fruit (fallen and maggoty fruit) has been used or that the preparation and despatch of the oil was made in unhygienic conditions.

*Condition 4.* — If the acidity (content of free fatty acid) is high, this indicates that the oil is not of first quality. But acidity alone is not the only criterion of quality. If for example a pure natural oil with an acidity of 2 (i. e. unacceptable) is mixed in equal proportions with a chemically refined pressed olive-oil, (also unacceptable) and which contains no acid, the blend with an acidity of 1.0 conforms with the conditions laid down by the Laboratory. It is with this fact in mind that condition 5 has been added to condition 4.

*Condition 5.* — This condition is particularly important and has been more than any other the subject of controversy. It will therefore be discussed at greater length.

It is a common practice to make blends of pure natural olive-oil with small quantities of refined and neutral pressed olive-oil, in order to build up large stocks and at the same time to deliver a uniform type throughout the season. If the refined oil is of good quality and is only used in small proportions in the mixture, it will not lower the quality of the unrefined oil mixed with it; on the contrary it will offer certain advantages. In normal conditions the quality of such a blend does not deteriorate during long storage.

If, however, the chemically refined oil constitutes an essential part of the blend, the quality of the mixture may fall during long storage, particularly if this refined oil is not of the best quality. This is the reason why the Laboratory, in accord with most of the oil experts of Tortosa, Reus and Borjas Blancas, have fixed the proportion of chemically refined oil in the blend at 30 per cent.

Certain people have pointed out that blends with as high a proportion of refined oil as 80 per cent. or even higher are used by Spanish and French canning factories. Nevertheless, as a result of systematic experiments made by the Laboratory in the canning of brislings and small herrings in blends of varying proportion of natural and refined olive-oil, the conclusion was reached that a large proportion of refined oil is

not very good for these fish. This became increasingly clear after successive periods of storing. The determination of the amount of refined pressed oil in a blend is made by the visual method (method of G. Lunde and F. Stiebel) and the results of the analyses of the Laboratory appear in its table under the title: Maximum fluorescence in blue. If the index under this heading is below 130 the oil is natural. As the proportion of refined oil rises, so the index also rises and reaches about 600 for pure chemically refined pressed oil.

*Condition 6.* — Refined extraction oil, also called sulphide, oil extracted from olive-cakes by carbon bisulphide and trichlorethylene respectively, is not considered in oil-producing countries as an edible oil; it is employed for industrial purposes.

*Condition 7.* — All olive-oils, of whatever type, precipitate solid fats at a sufficiently low temperature and continue to do so as the temperature falls until they eventually solidify. Accordingly, brislings and small herrings canned in olive-oil, when stored at a low temperature, contain particles of fats which spoil the appearance of the product and cause complaints from customers. We have noted that oils of various origins deposit fat crystals at various temperatures. The chilling test carried out by the Laboratory (drying, filtering and storing of the sample for a day at a temperature of  $+8^{\circ}\text{C}$ . and for three days at  $+4^{\circ}\text{C}$ .) showed that Spanish oils both from the south and north of the country give no precipitation in the above conditions.

Generally speaking, the oils of Tunisia and Algeria show less satisfactory results in the precipitation test than the Spanish oils, and the quantity of fat precipitated increases the further south the origin of the oil.

In the testing of the samples in winter on the dockside, it is possible that the interior of the barrels is coated with a layer of fat crystals. Accordingly, the staff of the Laboratory see that the olive-oil is well stirred in the barrel before the test. If the amount of solid fats is too high for a fair test to be made, a number of barrels are sent to the Laboratory, where the oil is electrically heated and clear and well mixed samples can be taken.

*Condition 8.* — The iodine index is characteristic of a large number of edible oils. For olive-oil this index is so low (79-88) that any blend with another edible oil would make it exceed 90.

*Condition 9.* — Chemical reactions causing rancid taste and odour give rise to new substances, in small quantities, which can be chemically revealed by coloured reactions, even before the rancidity can be detected by our senses. The Kreiss index is a criterion of the age and conservability of the oil.

*Condition 10.* — A natural olive-oil, well filtered, has a low content in ash, which is obtained by complete combustion of the oil. A chemically refined olive-oil may contain dissolved soap suds, if it is not sufficiently washed after the free acids in the oil have been neutralized by the alkaline soda. This soap reduces the conservability of the oil.

G. R.

**BAKING QUALITY TESTS.** — The valuable "Bibliography of Baking Quality Tests", issued by the Imperial Bureau of Plant Breeding and Genetics in 1934, has been brought up to date by the publication of a supplement which contains titles of papers from 1933 to 1938 inclusive.

Some of the papers noted have been abstracted in "Plant Breeding Abstracts" but many, because of their specialist nature have not been reviewed and will thus become available to workers of the subject.

A note of volume and abstract number in the margin indicates where an abstract may be found in "Plant Breeding Abstracts", and the titles are arranged alphabetically according to authors. Given sufficient demand, further supplements are promised from time to time.

## TECHNICAL BIBLIOGRAPHY \*

BACCALARIO Carlo, *Le industrie agrarie* (Enologia-Caseificio - Oleificio), Udine, (Istituto delle edizioni accademiche) 1938, 351 o., tables, illustrated.

[This important work published under the title of *Agricultural industries* is a survey of questions in regard to oenology, milk products and olive-oil, with special considerations regarding the development of these industries in Italy.

Each subject is treated in a series of well documented and sufficiently detailed chapters, which give a precise and clear idea of the particular question. The section on oenology is the fullest and most complete. It includes an introduction and fourteen chapters: 1. The localization of the wine industry. — 2. The cisterns for wine making. — 3. The first stage: the grapes. — 4. The vintage and the must. — 5. The neutralization of musts. — 6. Alcoholic fermentation and selected *ferments*. — 7. The control of the turgid fermentation. — 8. — Drawing off, pressing and utilization of weak wines. — 9. Supervision of the neutralization and conservation of wines. — 11. Geographical distribution of wines in Italy. — 12. The adulteration of wine. — 13. The adulteration of wine in relation to the law. Tasting and analyses for commercial valuation. — 14. Vinegar and its manufacture.

The section on milk and dairy products includes an introduction and eight chapters: 1. The raw material: milk. — 2. Rapid method of analysis for the commercial grading of milk. — 3. Milk hygiene. — 4. The localization of the cheese industry. — 5. Butter manufacture. — 6. Cheese manufacture. — 7. Cheese products in Italy. — 8. By-products of the dairy industry.

The section on olive-oil also consists of an introduction and eight chapters: 1. The olive and the oil. — 2. The picking and preparation of olives. — 3. The localization of the oil industry. — 4. The extraction of the oil. — 5. The neutralization and conservation of the oil. — 6. Alterations and adulterations of olive-oil. — 7. Tasting and the classification of fine oils. — 8. The by-products of the oil industry.

This book constitutes a real course in the technique of agrarian industry, and describes very clearly the present state of these three important agricultural industries. It will be found useful not only by farmers but also by experts.)] A. P.

MATAGRIN A., *Le soja et les industries du soja: Produits alimentaires, huile de soja, lécithine végétale, caséine végétale*. Gautier-Villars, Imprimeur-Editeur, 55, Quai des Grands Augustins, Paris VI (1929), 390 p. 46 illustrations, price: 60 francs.

[The A. aims at collating as far as possible all that has so far been written of the plant and bean, and the industrial uses of soya. For this he has made use of most of the works hitherto published on the cultivation and uses of the soya bean. He desires, in condensing the literature on soya in a single handy-sized volume, to aid French enterprise to develop the soya bean industry and to encourage French farmers to regard this crop more favourably.

The book is divided into seven chapters supplemented by a bibliography. These chapters are on: The agricultural, industrial and commercial history of the soya bean; 2. the botany and agronomy of the soya; 3. the general chemistry of the soya; 4. the soya in food preparations and manufactures; 5. the industries of soy bean oil and by-products; 6. the industry of vegetal lecithin; 7. the industries of vegetal casein and plastics with a soya basis.

The A. deals chiefly with the industries and the different uses of soya beans. He has succeeded in gathering the fullest information on all kinds of preparations from soya and enters into the fullest details of the industry and the chemistry of these products. His book, which does not deal at length with questions directly interesting farmers or agronomists, is on the other hand of first importance to anyone interested in the soya bean industry. Technicians will be glad to have assembled in a single volume all the information at present available on this subject. A work of this kind was needed in French.

J. L.

\* Reviews of publications received appear under this heading.

GALLINAI, P. J., BERGALLI U. L., CAMPAL, F. E., LEONARI A. L., and ROSENGURTT B., *Estudios sobre praderas naturales del Uruguay*. Montevideo, 1938, 208 p., tables, illustrations, bibliography, résumés in English.

[This work, unpublished at the beginning of 1938, represents a first contribution to the study and solution of an important agricultural and stock-breeding problem of Uruguay: that of a better understanding and utilization of the permanent or virgin meadows of the country.

This study, which has required four years of methodical work, is divided into three parts. The experiments were carried out in the south and southwest of Uruguay. First there were set up a certain number of experiment stations which proceeded to analyze the soils and fodder obtained in the first four cuttings: qualitative and quantitative botanical analyses with statistical comments. Later, the general characteristics of the Palleros zone were studied (geological and agrogeological notes, climatology principal morphological characteristics, etc.); a large amount of experimental work is described on the various fodder species which grow wild in this area, on the natural conditions and the means of improving them.

The second part of the work is devoted to the study of yields (losses of water on dry lands, cyclical variations in yield, production of various types of meadows, etc.) to geographical influences on fodder production (action of various soil elements, climatic influences, etc.) and to the quality of the fodder (average chemical composition of fodder of the Palleros meadows, chemical composition at different seasons, quality of the various types of meadows studied, etc.).

The third part examines the utilization of permanent meadows, particularly the economic value of fodder yields, the optimum and maximum producing capacity of meadows, the means of increasing the yield of permanent meadows, the natural selection of the fodder flora and the most suitable methods of attaining these ends.

Each of the very detailed chapters, comprises also a résumé in Spanish and English. A map of Uruguay at the end shows where the area studied is situated.

The conditions of Uruguayan stock-breeding are special: 7 million cattle and 15.5 million sheep on a territory of 18.7 million hectares and with 2 million inhabitants. It is interesting therefore to learn of the present evolution of the most important branch of the economic life of the country as the result of an attempt to transform the composition of the virgin meadows with the object of better fodder production.] A. P.

### DISCOVERIES AND CURRENT EVENTS \*

#### Germany: Further Records of the Colorado Beetle (*Leptinotarsa decemlineata*) in 1938 †

During the period from July 1 to October 13, 1938, the Colorado beetle was again reported in 1695 communes in the western area of the Reich.

The beetle was reported for the first time in the following 73 districts: Untertaunus (46 communes), Unterlahn (26 communes), Ahrweiler (25 communes), Kochen (23 communes), St. Goarshausen and Schleiden (each 20 communes), Dieburg (16 communes), Gross-Gerau (13 communes), Kirchheimbolanden and Limburg (each 12 communes), Wetzlar (10 communes), Oberlahn (9 communes), Main-Taunus, Neuenburg, Neustadt a. d. W. and Unterwesterwald (each 8 communes), Offenbach, Oppenheim and Usingen (each 7 communes), Dillkreis, Friedberg and Lahr (each 5 communes), Darmstadt and Oberbergischer Kreis (each 4 communes), Alzenau, Aschaffenburg, Frankfurt, Lohr, Oberndorf, Obertaunus, Oberwesterwald, Schotten and Siegen (each 3 communes), Biedenkopf, Calw, Erkelenz, Gelnhausen, Grevenbroich, Cologne, Leonberg, Nagold, Olpe, Ravensburg, Rottweil, Stockach and Wittgenstein (each 2 communes), Altena, Altenkirchen, Arnsberg, Baden-Baden, Backnang, Böblingen, Bidingen, Ehingen, Essen, Hechingen, Heilbronn, Kempen, Krefeld, Mainz, Marktheidenfeld, Maulbronn, Meschede, Mosbach, Mörs, Pforzheim, Rees, Rheydt, Schwäbisch-Gmünd, Sigmaringen, Tuttlingen, Überlingen and Wattenscheid (each 1 commune).

For records previously made in other parts of Germany, see this *Bulletin*, 1938, No. 8, p. 169, No. 10, p. 213, and No. 11, p. 241.

#### Belgium: The Colorado Beetle in 1938 §

The year 1938 was marked by a notable increase in the number of foci of *Leptinotarsa decemlineata* and by a northward extension of the areas attacked by the Colorado beetle.

While in 1937 the Colorado beetle was reported in 17 communes with 39 foci, in 1938 more than 1200 communes were attacked by this pest.

\* Under this and the next heading the countries are arranged in French alphabetical order.

† Communication from the Biologische Reichsanstalt für Land- und Forstwirtschaft, Berlin-Dahlem, official correspondent of the Institute.

§ Communication from Prof. R. MAYNÉ, Director of the State Entomological Station, Gembloux, transmitted by the official correspondent of the Institute, Prof. E. MARCHAL, Director of the State Phytopathological Station, Gembloux, Belgium.

The rapid spread of the insect over Belgian territory, coinciding with serious infestations in other European countries, is due to the mass flight of insects from the south; these insects settled in swarms in Belgium and even further north, creating new foci. The latter were scattered throughout the country as follows:—

Brabant . . . . .	146	communes affected
West Flanders . . . . .	188	» »
East Flanders . . . . .	214	» »
Hainault . . . . .	313	» »
Liège . . . . .	33	» »
Luxemburg . . . . .	114	» »
Namur . . . . .	150	» »
Antwerp . . . . .	37	» »
Limburg . . . . .	38	» »
Total . . . .	<u>1233</u>	<u>communes affected</u>

The insects appeared in all communes as more or less considerable localized foci; in several cases only one insect was captured.

The first of the foci was discovered on June 4 at Esplechin, Hainault and the last on October 17 at Stavelot, Liège.

In one instance, the Colorado beetle was discovered on henbane.

Control activities were intensified to meet the new situation.

Surveys were carried out by the schools and by private individuals; treatment was applied under the direction of experts from the Department of Agriculture; labour, equipment and materials were supplied at first and until July, by the Ministry of Agriculture; later the communes took part in the control campaign directly, supplied with material at reduced prices by the Government.

#### **Eritrea: *Locusta migratoria migratorioides* \***

During the first ten days of October, 1938, hoppers of *Locusta migratoria migratorioides* were reported from the hottest areas, *i. e.*, the low-lying plains in the west and in the Seraé and Atchelé Guzai plains, sheltered from the cold night winds.

About the middle of the month abundant new hatchings were reported from the entire Hamasien area and from western and eastern Tigray.

Many large swarms coming from the low-lying plains in the west and flying towards the eastern low-lying plains passed over the high plateaux in the course of the month. Many came from the Kassala area, and the passage of enormous swarms flying towards the interior of Eritrea was reported daily from the Sudan frontier.

In the low-lying plains of the west also, numerous hoppers became fully developed and spread towards the high plateaux. It was found impossible to

\* Communication from Dr. LUIGI M. BOLOGNA, Chief of the Agricultural Office of Eritrea, Asmara, transmitted to the Institute by the Government of the Colony.

deal with them in this region, owing to the nature of the land, to the scantiness of the population and to a recrudescence of malaria.

In the hatchings reported from the neighbourhood of Addi Ugri, Addi Quala and Decamerè, the presence of hoppers of the *transiens* phase was frequently observed.

The parasite mentioned in the September report [see this *Bulletin*, 1938, No. 12, p. 265], appears to belong to the genus *Trombidium* (*T. holosericeum* L. ?). The insects carrying this parasite, however, showed no signs of being affected by its presence.

Instances of locusts carrying the *Trombidium* were frequently found in all the swarms from which it was possible to obtain specimens.

Another parasite was reported in the low-lying western plains and in the Schirè. So far it has been impossible to examine any specimens, but from the description given it would appear that this is a fungous parasite, probably *Empusa grylli*.

The crops, which were almost ready for harvesting, were very seriously damaged. Control measures were organized by the political authorities, the work being carried out by experts working under the instructions of the Agricultural Office of the Colony. As hoppers were found in the middle of the crops and poisoned bait did not attract the insects, the work was exceedingly difficult.

Threshing was impossible and fire-throwers were of no avail in arresting the invasion. This system gave excellent results, however, in clearing the railway at Arbaroba and Agat.

To prevent danger to motor traffic from the hopper bands covering the asphalted surface of the principal highways, the roads were sprayed with 3 per cent. solution of sodium arsenite. This method gave good results.

### Luxemburg (Grand Duchy of): The Colorado Beetle Situation in 1938 \*

In 1938, the Colorado beetle (*Leptinotarsa decemlineata*) was reported in the following districts of the Grand Duchy:—

Luxemburg city area . . . . .	8	communes infested with	10 foci
Luxemburg Canton . . . . .	14	»	»
Capellen » . . . . .	18	»	»
Esch » . . . . .	29	»	»
Mersch » . . . . .	12	»	»
Echternach » . . . . .	6	»	»
Grevenmacher » . . . . .	11	»	»
Remich » . . . . .	13	»	»
Diekirch » . . . . .	13	»	»
Rédange » . . . . .	25	»	»
Wiltz » . . . . .	15	»	»
Clervaux » . . . . .	11	»	»
Vianden » . . . . .	1	»	»
Total . . .	176	communes infested with	570 foci.

\* Communication from the official correspondent of the Institute, Dr. VICTOR FERRANT, Chief of the Phytopathological Service, Luxembourg, Grand Duchy of Luxembourg.

### Mozambique: Locust Movements \*

No locusts were reported in the Province of Nyassa (Porto Amelia and Mozambique districts) during August 1938. On the 18th, however, a large swarm of red locusts (*Nomadacris septemfasciata*) from the uplands of 'Gorongóza' (Manica and Sofála territories) passed over the Barué district in the Tete region, Zambesi Province.

No locusts were observed in the Inhâmbane and Lourenço Marques districts, Sul do Save Province.

Hence as compared with July, the locust situation in the Colony may be considered unchanged. It is probable, however, that this will soon be altered, but only in the west central and northwestern areas, where further invasions are expected owing to the activity of *N. septemfasciata* in the neighbouring colonies on the west.

### Southern Rhodesia: Locust Invasion, 1932-38 †

Monthly Report No. 70. September, 1938.

Numerous swarms of the red locust (*Nomadacris septemfasciata*, Serv.) have been reported during the month. Reports have been received from eleven districts in Mashonaland, namely:— Lomagundi, Melsetter, Inyanga, Rusapi, Sebungwe, Umtali, Bekita, Hartley, Gutu, Makoni and Chibi; and from five districts in Matabeleland, namely:— Gwelo, Bulalima-Mangwe, Bulawayo, Sebungwe and Matobo.

Many of the swarms have been described as large. There appears to be a general tendency for the swarms to move in a southerly direction. The Melsetter district has been invaded by many swarms from Portuguese East Africa. Some damage to winter crops and fruit trees have been notified.

The development of colour has passed the deepest red stage.

### Italian Somaliland: Locusts §

No locusts were reported in the Colony in October and November, 1938.

\* Communication from Mr. C. DE MELLO VIEIRA, Acting Chief of Agricultural Services, Section of Entomology, Lourenço Marques, Mozambique.

† Communication from Mr. J. K. CHORLEY, Acting Chief Entomologist, Agricultural Laboratory, Department of Agriculture, Salisbury, Southern Rhodesia.

§ Communication from Dr. MARTINO VIDOTTO, Acting Chief of the Agricultural Services of Italian Somaliland, Mogadiscio, transmitted to the Institute by the Government of the Colony.

## LEGISLATIVE AND ADMINISTRATIVE MEASURES

**Algeria.** — A Decree of September 26, 1938 regulates the use of hydrocyanic acid gas for disinfecting plant products, growing plants and soils, and also greenhouses and warehouses where foods are handled or stored. (*Journal officiel de l'Algérie*, Alger, 7 octobre 1938, XII<sup>e</sup> année, n<sup>o</sup> 40, p. 1702-1704).

\*\*\* A Decree of the President of the French Republic, dated September 28, 1938, regulating the production, sale and transport of wheat seed in Algeria, provides, *inter alia*, that no dealer may transport, for purposes of sale, place on sale or sell as wheat seed any lots of grain containing weed seed and bunted wheat (*Tilletia tritici*). (*Ibid.*, 4 novembre 1938, n<sup>o</sup> 44 p. 1992-1993).

\*\*\* A Decree issued by the President of the French Republic, dated October 31, 1938, provides, *inter alia*, that the Government General of Algeria, if a species of wild animal is in danger of extinction, may prohibit not only the hunting of this animal, but also its destruction by a landowner or farmer, although compensation may be allowed to those landowners who produce evidence of the damage done by the animal to their crops.

The Governor General may approve the formation of departmental federations of hunting societies with the object of improving hunting in Algeria, especially by the preservation of game, the creation of reserves, breeding, general protection, the protection of birds useful to agriculture and the destruction of noxious animals. (*Bulletin de l'Office des Renseignements agricoles*, Paris, 15 novembre 1938, année 1938, n<sup>o</sup> 22, p. 583).

**Germany.** — By Decree dated September 24, 1938, the Ministry of Agriculture modified the Decrees dated October 20, 1937, January 19, March 5, May 6 and June 16, 1938 [see this *Bulletin*, 1938, No. 2, pp. 29-30; No. 6, p. 125; No 7, p. 149, and No. 9, pp. 193-194] and granted further facilities for the importation and transit of horticultural produce from France, Belgium, Luxemburg and Switzerland.

Chicory may enter the country during the period from October 15 to November 14, and celery stalks from September 10 to November 14. (*Amtliche Pflanzenschutzbestimmungen*, Berlin, 1. December 1938, Bd. X, Nr. 8, S. 220).

**Angola.** — The Minister for the Portuguese Colonies, by Decree No. 28:573 of April 7, 1938 has authorized the Governor General of Angola to include in the 1938 budget a special credit of 500,000 'angulares' for locust control in the Colony. (*Diário do Governo*, Lisboa, 7 de abril de 1938, I série, núm. 80, pág. [639]).

**Argentine Republic.** — Decree No. 115,421 of September 30, 1937 authorizes the application of the provisions of Decree No. 108,722 of June 21, 1937, relative to the establishment of a plant disinfection station at the port inspection bureau under the control of the Plant Protection Department of the Ministry of Agriculture. (*Boletín Oficial de la República Argentina*, Buenos Aires, 23 de agosto de 1938, año XLVI, núm. 13,223, pág. 10932).

\*\* Decree No. 11,358 of September 2, 1938 modifies Decree No. 83,732 of June 3, 1936 [see this *Bulletin*, 1936, No. 12, p. 265] relative to the import of plants, parts of plants and other plant products. (*Ibid.*, 7 de septiembre de 1938, núm. 13,235, pág. 11750).

\*\* Law No. 12,559 of September 30, 1938 authorizes the expenditure of 10 million 'pesos' for the control of locusts [*Schistocerca paranensis*] during the year 1938-39. (*Ibid.*, 17 de octubre de 1938, núm. 13,268, pág. 14072).

**Australia (New South Wales)** \* — Ordinance No. 50, as made by Proclamation of August 31, 1938, published on September 2, 1938, prescribes methods of eradication of noxious plants in general and methods of eradication of *Erythroxylum coca*, *Papaver somniferum*, *Cannabis sativa*, *Homeria collina*, *Senecio jacobaea*, and *Ailanthus glandulosa*.

Three forms are appended to the said Ordinance.

\*\* By Proclamation of September 14, 1938, published on September 16, 1938, Ordinance No. 50 is amended in form 1.

**France.** — By Decree of October 11, 1938 the composition of the advisory Committee for plant protection has been changed. (*Journal officiel de la République française*, Paris, 15 octobre 1938, LXX<sup>e</sup> année, n<sup>o</sup> 242, p. 11999-12000).

**Italy.** — By two Ministerial Decrees of September 17, 1938, the application of the exchange duty at the reduced rate of 0.75 lire per cent. is extended from October 1, 1938 to the parasiticides sold in commerce as 'E. I. A.' ('Emulsione Italiana Antiparassitaria') and 'Solforamica S. P. A.' (*Gazzetta Ufficiale del Regno d'Italia*, Roma, 8 ottobre 1938, anno 79<sup>o</sup>, n. 231, pp. 4242-4243).

\*\* A Ministerial Decree of September 20, 1938 lays down the regulations for the import of foreign potatoes intended solely for planting, for the 1938-39 season. (*Ibid.*, 27 settembre 1938, n. 221, p. 4055-4056).

\* Communication from the Prime Minister's Department, Canberra, Australia, to the International Institute of Agriculture.

**Libya.** — By Decree dated January 31, 1938, issued by the Governor General of Libya, only expressly authorized firms and persons may plant nurseries and cultivate for sale or deal in plants, portions of plants and seeds for cultivation, including ornamental plants.

Permits to continue operating a nursery, to cultivate for sale or to sell plants portions of plants or seeds, or to perform such operations, will be granted by the Governor General of Libya on the recommendation of the Agricultural Office attached to the Prefecture of the area where the concern is situated. Where required this Office will make any inquiries necessary for purposes of control.

These permits may be discontinued at any moment for an indefinite period, or even revoked, should the periodic control visits of the above-mentioned Office reveal the presence of produce attacked by parasites or by dangerous and contagious diseases.

In case of infections declared as dangerous, the Office may order the disinfection of the produce at the expense of the interested party, according to the advice and in the presence of an expert attached to the said Office, or may order the partial or total destruction of the produce.

All nurserymen and traders in plants, parts of plants and seeds are required to declare to the Agricultural Office of their respective Prefecture, any dangerous and transmissible animal or plant parasites, found on their plants or produce. (*Agricoltura Libica*, Tripoli, dicembre 1938, anno VII, n. 12, pp. 565-567).

**Mexico.** — By 'Acuerdo' of September 5, 1938, avocados grown in Sinaloa State may be transported to Sonora State and the Territory of Lower California if accompanied by a certificate testifying that these fruits are not attacked by the 'barrenador del hueso' (*Heilipus lauri*) or by the fruit fly (*Anastrepha* sp.). (*Diario Oficial*, México, 26 de septiembre de 1938, tomo CX, núm. 21, pág. 2).

\* \* The 'Acuerdo' of September 7, 1938 modifies the local quarantine regulation No. 1 relative to the control of the pink bollworm [*Platyedra gossypiella*] in regard to time of harvesting and the cleaning of cotton fields. (*Ibid.*, págs. [1] y 2).

**Peru.** — A Resolution of July 13, 1938 provides for the consideration of a plan for the control of grape phylloxera in the Departments of Moquegua and Tacna. (*El Peruano*, Lima, 6 de agosto de 1938, año 98, tomo II, trim. III, núm. 174, pág. 776).

**Poland** \* — By Ministerial Decree, dated March 2, 1938, the voivodes are authorized to apply compulsory measures against the beet leaf bug (*Piesma quadrata*); to designate areas where destruction shall be compulsory and deter-

\* Communication from the official correspondent of the Institute, Prof. Dr. STANISŁAW MIN-KIEWICZ, Chief of the Department of Entomology, Government Institute for Agricultural Research, Puławy, Poland.

mine the duration of, and methods to be adopted for the control measures; to request the collaboration of state officials, of the staff appointed by the Chamber of Agriculture and of the Agricultural Societies.

**Tunisia.** — By Decree of June 8, 1938, the proprietors of vineyards are formed into a compulsory association. This association is entitled the 'Syndicat général obligatoire des viticulteurs de Tunisie' and is required, *inter alia*, under the control of the Administration:—

(1) To inspect vines, to ascertain the presence of grape phylloxera and, on request of the Administration, to control phylloxera and to apply suitable treatments against the various pests or diseases of the grape-vine;

(2) To assist in forming new plantations with American plants, by establishing fields of mother American plants, district and local nurseries for the production of rooted and grafted plants to replace vines destroyed or attacked by phylloxera, and experimental vineyards for determining the best vine stocks. (*Bulletin de la Direction des Affaires Economiques*, Tunis, 2<sup>e</sup> trimestre 1938, XLII<sup>e</sup> année, n<sup>o</sup> 173, p. 146-150).

**Yugoslavia.** — Decree No. 40049-II, dated June 15, 1938, lays down the methods to be adopted in the campaign against the San José scale (*Aspidiotus perniciosus*) in the territory administered by the City of Belgrade. (*Službene Novine*, Beograd, 21 juna 1938, godina XX, broj 136-XLI, str. 784-786).

[The powder which Mr. D'Amico calls 'Asporital' utilized in the control of grain rusts (*Puccinia* spp.) brings about an increase in grain production, partly due, according to the A., to the definite anticryptogamic efficacy of the preparation. This preparation stimulates cereal growth and also acts as a mild weedicide. Another effect of 'Asporital' which has to be confirmed is that on the microscopic fungi of the surface layers of the soil].

## NOTES

Fourth Conference of the International Committee for the Mutual Study of the Control of the Colorado Beetle. — This Conference will meet on February 2, 3 and 4, 1939 at Wageningen, Netherlands.

Official Correspondents. — Dr. L. N. SETH, Mycologist, Department of Agriculture of Burma, at Mandalay, and Mr. L. J. S. LITTLEJOHN, Phytopathologist, Department of Agriculture of Cyprus, at Nicosia, have been appointed official correspondents to the International Institute of Agriculture on questions relating to plant protection in their countries.

---

Prof. ALESSANDRO BRIZI, *Segretario generale dell'Istituto, Direttore responsabile.*

# INTERNATIONAL BULLETIN OF PLANT PROTECTION

---

## DISCOVERIES AND CURRENT EVENTS \*

### Germany: Further Records of the Colorado Beetle (*Leptinotarsa decemlineata*) in 1938 †

During the period from July 1 to November 13, 1938 the Colorado beetle was reported for the first time in the following 9 administrative areas: Rheinisch-Bergischer Kreis (2 communes), Borken, Crailsheim, Giessen, Hall, Marbach, Marburg, Münsingen, and Rhein-Wupperkreis (each one commune).

For reports made previously in other administrative areas of Germany, see this *Bulletin*, 1938, No. 8, p. 169; No. 10, p. 213; No. 11, p. 241 and 1939, No. 1, p. 1.

### Australia: Notes on Plant Diseases Recorded in New South Wales for the Year Ending 30th June, 1938 §

#### CEREALS AND FIELD CROPS.

Wheat crops were relatively free from disease. Flag Smut (*Urocystis tritici*) although serious on susceptible varieties is now becoming of less consequence as resistant varieties are so widely grown. Pseudo-black chaff was noted in several varieties but was of little importance. Ergot (*Claviceps paspali*) was again widespread in paspalum in coastal areas. Kernel smut (*Sphacelotheca sorghi*) caused losses in broom millet crops. Potato crops in coastal areas suffered severely from an outbreak of late blight (*Phytophthora infestans*). Less serious infections were recorded in the case of brown rot (*Bacterium solanacearum*), early blight (*Alternaria solani*) and tomato spotted wilt (virus) in potatoes. Potato leaf roll is still the most common virus disease in this crop.

It was estimated that maize yields were reduced by approximately 12 per cent as a result of root, stalk and cob rots (*Gibberella saubinetii*, *G. fujikuroi* var. *subglutinans* and *G. moniliformis*). American maize smut (*Ustilago zaeae*)

\* Under this and the next heading the countries are arranged in French alphabetical order.

† Communication from the Biologische Reichsanstalt für Land- und Forstwirtschaft, Berlin-Dahlem, the official correspondent of the Institute.

§ Communication from the official correspondent of the Institute, Dr. R. J. NOBLE, Biologist, Department of Agriculture, Sydney, New South Wales, Australia.

was recorded in a commercial area of maize. The crop was destroyed by fire and the area subjected to quarantine regulations with a view to checking spread of the disease.

Major losses in pea crops resulted from *Fusarium* and *Rhizoctonia* root rots. Lack of root nodules was associated with a crop failure in one area. Leaf mildew (*Cladosporium fulvum*) was again the most serious disease of glass-house tomato crops. Spotted wilt (virus) was the most serious disease of tomatoes in the outdoor metropolitan crops. Canker (*Aplanobacter michiganense*) was widespread in tomato crops generally.

*Sclerotium rolfsii* and *Sclerotinia libertiana* affected many vegetable and ornamental crops; *S. rolfsii* was recorded on onions for the first time in this State.

#### FRUIT CROPS.

Black spot (*Phoma citricarpa*) seriously affected main crop Valencia oranges in coastal areas. This crop also was subject to unusual mould attack (*Penicillium* spp.) which also was recorded in a heavy second crop of oranges which set after breaking of the 1936-37 dry period. *Septoria depressa* spot of citrus was recorded from inland irrigation areas.

Powdery mildew (*Oidium* sp.) of grapes was unusually prevalent during a period of high humidity; shedding of berries and breakdown conditions in grapes appeared to be associated with low temperature and low soil moisture conditions respectively.

Black spot (*Venturia inaequalis*) was less serious than usual on apples. Freckle (*Cladosporium carpophilum*) occurred for the first time in many years on early maturing peach varieties; it was severe in untreated areas of later types. Rust (*Puccinia pruni-spinosae*) caused losses in coastal peaches and on unsprayed canning varieties of inland irrigation areas.

A dieback condition in cherries caused extensive losses. Banana bunchy top (virus) is kept under control as a result of constant vigilance. "Rubbery" bananas of hard unpalatable texture were associated apparently with production areas of forest rather than "scrub" soils and with the incidence of low temperatures during later stages of development. Leaf Spot (*Cercospora musae*) followed incidence of prolonged summer rains in north coastal areas and resulted in severe defoliation, with consequent loss of size and quality in bananas. A pitted condition superficially resembling anthracnose developed extensively in bananas and appeared to be associated with chilling of winter grown fruit.

#### OTHER CROPS.

Ornamentals grown for market were subjected to serious losses by disease, e.g., Nematode (*Heterodera marioni*), *Fusarium* root rot and Bud rot (*Sporotrichum poae*) on carnations, Root rot (*Fusarium conglutinans callistephi*) on asters, Tomato spotted wilt (virus) and Crown rot (*Phytophthora cryptogea*) on Iceland poppies (*Papaver nudicaule*) and Scab (*Sphaceloma violae*) on violets.

**Eritrea: *Locusta migratoria migratorioides* \***

During the month of November 1938 many hoppers of the African migratory locust (*Locusta migratoria migratorioides*) were observed, chiefly in the 4th and 5th stages.

The starting point of the invasions was changed from the low-lying western plains to certain zones of the Tigrai. This locust is apparently extremely resistant to the cold night winds and goes to the high plateaux only during the warmest hours of the day.

It is said that an outbreak area has been found in Alalà, along the Gasc river.

Other hopper bands of less importance have been observed on the Rore, in the Hamasien territory and in the Acchelè Guzai.

The young adults have not yet moved in any definite direction; it has been noticed that a swarm coming from a given point may hover over a region and finally return to their starting-point. Such swarms, however, usually make for districts where fresh pasturage or standing crops may be found.

A swarm from Hamasien hovered over Ghinda and then descended towards the Damas plain whence, some days later, it returned to the plains at medium altitude, where it still remains. In the middle of the month there was a similar occurrence in Dancalia, since when no further reports have been received. A supervision and control service has been established along the Gasc river, baits being chiefly used and – in exceptional cases – flame-throwers. Much damage to crops has been averted by the prompt action of the staff engaged in the campaign.

**Mozambique: Locusts †**

During September 1938 no movements of locusts were registered in any of the three provinces of the Colony.

**Southern Rhodesia: Locust Invasion, 1932-1938 §**

Monthly Report No. 71. October, 1938.

During October numerous flying swarms of the red locust (*Nomadacris septemfasciata*, Serv.) have been reported. Most districts in the Colony have reported swarms except those in the extreme south and north west. Fifteen districts in Mashonaland have been invaded, namely: Charter, Chilimanzi, Gutu, Hartley, Inyanga, Lomagundi, Makoni, Mrewa, Marandellas, Mazoe, Melssetter,

\* Communication from Dr. LUIGI M. BOLOGNA, Director of the Agricultural Office Asmara, transmitted to the Institute by the Government of the Colony.

† Communication from M. ALBERTO COUTINHO SARAIVA, Director of the Section of Entomology Lourenço Marques, Mozambique.

§ Communication from Mr. J. K. CHORLEY, Acting Chief Entomologist, Agricultural Laboratory, Department of Agriculture, Salisbury, Southern Rhodesia.

Ndanga, Salisbury, Umtali, and Victoria, and seven districts in Matábeleland, namely: Bulalima-Mangwe, Gwanda, Gwelo, Insiza, Matobo, Nyamandhlovu, and Sebungwe.

The eastern districts have been heavily invaded by swarms from Portuguese East Africa.

Considerable damage has been caused to early grazing and some wheat crops have suffered.

New spring foliage on indigenous trees has been badly damaged.

The direction of flight has been variable.

### Switzerland: Outbreak of *Laspeyresia* (*Cydia*) *molesta* and *Ceresa bubalus* in the Country \*

The oriental peach moth (*Laspeyresia* [*Cydia*] *molesta* Busck), which is found throughout north Italy and, in France, in the Alpes-Maritimes and the Var, was discovered in Switzerland in 1937, in several localities of Ticino and in an orchard near Lausanne. It has probably penetrated into Ticino by natural migration from the neighbouring Italian districts which have been infested since 1934. At Lausanne, the insect was introduced by trade movements.

In 1938, the oriental peach moth was rare in Ticino, and the Lausanne focus did not spread; only a single larva was found there.

In the course of September 1938, the American membracid *Ceresa bubalus* Fab. was discovered in several orchards in central Valais, especially at Saxon and Sion where considerable damage was done on apple and pear trees. It would seem that the introduction was earlier than 1934.

## LEGISLATIVE AND ADMINISTRATIVE MEASURES

**Germany.** — A Decree of August 25, 1938 on the use of ethylene oxide combines in a single text the provisions of the Order of February 26, 1932 and the amendments of this Order introduced by the Decrees of October 10, 1934, October 19, 1935 and May 20, 1936 [see this *Bulletin*, 1932, No. 6, p. 99; 1935, No. 4, p. 85; 1936, No. 2, p. 31, and No. 8, p. 173].

Additions have been made to these provisions, rendering them clearer and more effective.

The precautionary measures intended to prevent the occurrence of fires and explosions have been made more stringent. It is enacted that on premises that have to be disinfected by means of ethylene oxide and on neighbouring premises, stoves are to be put out 24 hours at least before beginning fumigation.

\* Communication from the official correspondent of the Institute, Dr. H. FAES, Director of the Federal Experiment Station of Vine and Fruit Trees, Lausanne, Switzerland.

The use of ethylene oxide is prohibited in old houses where, owing to the condition of the structure, the rooms which are to be disinfected cannot be hermetically sealed.

Fumigation of buildings that are not isolated and of premises in inhabited buildings must be begun after 1 p. m. on the day appointed.

Permission to install movable ethylene oxide disinfection chambers will be given only if the chambers in question are to be installed inside uninhabited buildings or in the open air at a distance of at least 5 m. from any inhabited dwelling. Their construction must allow of effective heating and ventilation involving no risk to the neighbourhood. (*Amtliche Pflanzenschutzbestimmungen*, Berlin, 1. Oktober 1938, Bd. X, Nr. 7, S. 172-174).

\*\*\* On August 9, 1938 supplementary instructions were issued for the application of the Decree of July 1, 1938 relating to control of the musk rat [*Fiber zibeticus*] [see this *Bulletin*, 1938, No. 12, p. 270]. (*Ibid.*, S. 175-176).

**Germany (Brunswick).** — By Decree of July 4, 1938 relative to the destruction of yellow weed (*Galinsoga parviflora*), the control of this plant is made compulsory for all proprietors, occupants and holders of any land.

The plants of *G. parviflora* must be uprooted and destroyed on the spot by burning or by digging well into the ground. Any other system of destruction is forbidden, especially that of leaving the uprooted plants in the fields or roads, or throwing them into ditches, streams, on to manure heaps, etc.

This weed should be destroyed every year on all fields before July 1, exception being made for cereal fields, where operations will be carried out immediately after harvesting.

Plants which reappear after this preliminary clearing operation must be destroyed as soon as seen and before flowers are formed. They may be destroyed by any means which ensure definite killing off of growth.

Destruction operations will be under the control of the Plant Protection Service, police authorities and mayors. The last-named may set up Committees of two or three members for this purpose. The first inspection will take place after July 1 and at the latest July 15; further inspections will be made at intervals of about four weeks. (*Amtliche Pflanzenschutzbestimmungen*, Berlin, 1. August 1938, Bd. X, Nr. 6, S. 127-128).

**Germany (Prussia).** — By Decree of October 31, 1938 on the virus diseases of potatoes, planting of peach and apricot trees is prohibited in certain districts in Pomerania.

Any peach or apricot tree found to be withering and with no promise of fruit must be removed before March 15.

Peach and apricot trees are to be treated, during mild dry days between December and February, with an application of carbolineum.

Peach and apricot trees must be watched for the appearance of the aphid *Myzodes (Myzus) persicae*. Trees which, in spite of the treatment, are found to be infested by aphides, must be sprayed, immediately before or after flowering

with a preparation recognized as effective against aphides by the Central Plant Protection Service.

Spraysings must be made in accordance with the instructions of Plant Protection Service.

The administrative authority may arrange for spraying to be done directly by the Plant Protection Service at the expense of the person concerned who is obliged to render assistance. (*Amliche Pflanzenschutzbestimmungen*, Berlin, 1. Dezember 1938, Bd. X, Nr. 8, S. 221-222).

**Argentine Republic.** — By Decree No. 13.800 October 5, 1938, article 8 of the Decree No. 116.277 of October 9, 1937 is amended. The article now reads as follows: 'Certified seed potatoes imported into Argentina must be transported in the packing material in which they entered the country; a new label shall be affixed with the words: 'Semilla certificada de papa - Importada'.

'The new label will be affixed at the National Potato Market, if the goods enter by the port of Buenos Aires, and by the staff of the Plant Health Department, responsible for plant inspection at ports, if they enter by the port of Rio Gallegos'. (*Boletín Oficial de la República Argentina*, Buenos Aires, 31 de octubre de 1939, año XLVI, núm. 13.280, pág. 14.714).

**Australia (New South Wales)** \* — A Proclamation of August 31, 1938 indicates the plants declared to be noxious plants in the different portions of the State.

**Australia (Queensland).** — By Notification of October 19, 1938, Indian Hemp (*Cannabis sativa*), Opium Poppy (*Papaver somniferum*), and Coca Leaf (*Erythroxylum coca*) have been declared to be noxious weeds or plants in the State of Queensland. (*Queensland Government Gazette*, Brisbane, 22nd October, 1938, Vol. CLI, No. 94, p. 1706).

**Brazil.** — By Decree-Law No. 780 of October 12, 1938, an Experiment Station of Insecticidal Plants (Estação Experimental de Plantas Entomotóxicas), placed under the Ministry of Agriculture, was been set up. This Station is to undertake study, experimental trials and propagation of plants with insecticidal properties, especially those belonging to the genus *Lonchocarpus* (timbós), with a view to their utilization in control measures against crop pests. (*Diário Oficial*, Seção I, [Rio de Janeiro], 14 de outubro de 1938, anno LXXXVII, n. 238, pag. 20665).

**Belgian Congo.** — Ordinance No. 59/Agri, of April 19, 1938 relative to the cultivation, purchase of and trade in cotton, lays down, *inter alia*, that the Chief of Province is authorized to prohibit sowing cottonseed other than that supplied, or the quality of which has been verified by himself.

\* Communication from the Prime Minister's Department, Canberra, Australia to the International Institute of Agriculture.

The introduction of cottonseed into a province by private individuals is prohibited, unless previously authorized by the Chief of Province.

Whosoever cultivates or causes cotton to be cultivated is required, on the lands in question, to:—

(1) Top or destroy or have topped or destroyed according to the methods and at the times indicated by the Chief of Province, the plants, bolls and plant waste affected with diseases or pests which by the latter may specify.

(2) Uproot and burn cultivated cotton plants, collect and burn the bolls; these operations should be carried out immediately after harvesting and at the latest two months before the date determined for sowing.

The Chief of Province, on the proposal of the Chief of the Provincial Service of Agriculture and Colonization or of a qualified expert, and by decision posted up in the chief towns of the zones in question, may prohibit cotton cultivation in any given region for a whole season, with a view to eliminating any disease existing in this region or to checking the propagation of a disease infesting another zone. This prohibition may be renewed from year to year if necessary.

The Chief of Province, may also as a preventive measure, order the destruction of healthy plantations in an area open to cotton cultivation; against compensation representing the value of the plantation at the time of destruction, the amount being decided by the Chief of Province.

The Territorial Administrator, on the proposal of the Chief of the Provincial Service of Agriculture and Colonization or of a qualified specialist, may, with a view to preventing the spread of infestation, order immediate destruction by burning of cotton plants or plants in the field and of seed or harvested but unginned cotton affected by diseases or pests which it is not possible to control effectively by any other means.

If considered justified, the Chief of Province may in the above-mentioned cases grant to the party entitled a compensation equivalent at most to the value at the time of destruction of the plants, seeds and cotton burnt, and in the condition at the time when destruction was ordered.

The officers of or acting for the Territorial Service and the Agricultural Service may, with a view to studying the condition of cotton crops, at any time, even at night, inspect, fields planted with cotton whoever the proprietors.

All Territorial Administrators are required to inform without delay the Administrators of adjoining zones of the presence of any cotton diseases caused by insects or fungi, which have been officially reported to him by the Chief of the Provincial Service of Agriculture and Colonization or by a qualified expert.

All holders of unginned cotton are obliged to declare the quantities of this cotton and where stored.

This cotton should be ginned before the April 1 following for the districts south of the Equator, and before November 1 for the districts north of the Equator. After this date, the Chief of Province, on the proposal of an officer of the Service of Agriculture and Colonization, may order the burning of unginned cotton.

If there is a threat of disease, the time allowed before ginning may be reduced by the Chief of Province.

Besides withdrawal of the buying licence granted by the Territorial Administrator, penalties may be inflicted on whosoever has:—

(a) Purchased unginned cotton grown in the Colony by natives of the Congo or other African countries elsewhere than at the cotton markets or at the cotton-gins;

(b) Outside the above specified localities or outside the period fixed for the buying season, offered or caused to be offered to natives to buy their cotton;

(c) Before the buying season, offered or agreed to store native cotton and to practise the system of advanced payments on the crop.

All the seeds from cotton ginned by hand should be destroyed by fire or by any other means authorized by the Chief of Province. This operation will be carried out from day to day and, at the latest, within 24 hours following ginning, by and under the responsibility of the proprietor or lessee of the gins. The sale and purchase of these seeds are prohibited under penalty of a fine of from 100 to 1000 francs and confiscation of the seed.

Unless authorized by the Chief of Province, it is prohibited to transport or have transported unginned cotton bought from the natives from one zone to another.

The Chief of Province may order that the seed of cotton treated at the cotton-gin and requisitioned by him or by the Territorial Administrator, shall be disinfected within the period and in the manner determined by the said Chief of Province.

The Chief of Province may also authorize the export of these seeds outside the limits of the zone of operation of the cotton gin or the province. (*Bulletin Administratif du Congo belge*, Léopoldville, 25 avril 1938, 27<sup>me</sup> année, n° 8, p. 296-318).

**France.** — Two Decrees of October 28, 1938 modify the Decree of October 13, 1934 relative to the award of grants to the victims of agricultural disasters (hurricanes, floods, frosts or hail). (*Bulletin de l'Office de Renseignements agricoles*, Paris, 15 novembre 1938, année 1938, n° 22, p. 582-583).

**Italy.** — Royal Decree-Law No. 1622 of September 5, 1938, made the following provisions:—

A credit of 1,500,000 lire is granted to the Ministry of Agriculture and Forests for each financial year from 1938-39 to 1941-42, for the payment to citrus fruit growers of a contribution towards any expense they shall incur in connection with the campaign against the 'mal secco' [*Deuterophoma tracheiphila*] in Sicily; and the reconstitution of plantations destroyed or infected during the seasons 1938-39 to 1941-42.

The maximum of 300,000 lire fixed by Royal Decree-Law No. 115 of January 18, 1937, which came into force under Law No. 576 of April 3, 1937 [see this *Bulletin*, 1937, No. 4, pp. 70-71, and No. 7, pp. 155, 156] for payment to

citrus fruit growers of a Government contribution towards the expenses incurred for the 'mal secco' campaign in Sicily and the reconstitution of plantations destroyed or infected during the season 1935-36, has been raised to 450,000 lire.

The Ministry of Agriculture and Forests is authorized to contribute toward the expenses incurred by farmers for the campaign against scale insects and other animal and plant parasites of citrus trees and fruits during the seasons 1939-1948.

For this purpose the Ministry in its estimated expenditure has allocated a credit of 4 million lire for the financial year 1938-39 and further credits of 4.5 million lire for each of the financial years from 1939-40 to 1947-48.

The Ministry of Agriculture and Forests is further authorized to make grants:—

(a) Towards the expense reconstituting plantations of: peach trees destroyed or infested by 'moria'; pear and plum trees destroyed or infested by *Parlatoria*, almond trees destroyed or infested by root rot or 'verde secco', and filbert trees destroyed or infested by 'verme del legno', on condition that such reconstitution shall be effected subsequent to the issue of the present Decree and not later than the season 1939-40;

(b) Towards the expense of reconstituting chestnut plantations destroyed or infested by ink disease [*Phytophthora cambivora*], provided that it shall be carried out after the publication of the present Decree and not later than the season 1947-48;

(c) Towards the expenses of the campaign against animal and plant parasites of peach, apple, pear, chestnut, cherry, plum, apricot and almond trees and fruit, provided it is carried out after the issue of the present Decree and not later than the season 1947-48;

(d) To syndicates of fruit-growers set up in conformity with Law No. 897 of June 18, 1931 [see the *Bulletin*, 1931, No. 9, pp. 166-167] with object of ensuring the whole or partial payment of interest on loans that shall have been necessary for the campaign prescribed for the seasons 1938-39 and 1939-40, against animal and plant parasites of peach, apple, pear, apricot and almond trees and fruit;

(e) To syndicates for fruit-growing in provinces where the production of dried figs is of great importance, as contributions towards expenses incurred for the construction of plant for the disinfection of dried figs and the purchase of cases for the disinfection and conservation of the product on farms;

(f) Towards expenses incurred for the disinfection of dried figs after the issue of the present Decree and not later than the season 1947-48;

(g) Towards the expenses of organizing and launching syndicates for fruit-growing, established after 1936 in conformity with the Law No. 987 of June 18, 1931.

For the purpose of providing the amount required for the above-mentioned contributions the Ministry of Agriculture and Forests has allotted the following credits:—

(1) In respect of par. (a): 402,500 lire for each of the years 1938-39 and 1939-40;

- (2) In respect of par. (b): 280,000 lire for each year from 1938-39 to 1947-48;
- (3) In respect of par. (c): 2,955,000 lire for each year from 1938-39 to 1947-48;
- (4) In respect of par (d): 455,000 lire for the years 1938-39 and 1939-40;
- (5) In respect of par. (e): 210,000 lire for the year 1938-39;
- (6) In respect of par. (f): 300,000 lire for each year from 1938-39 to 1947-48;
- (7) In respect of par. (g): 820,000 lire for the year 1938-39.

The Minister of Agriculture and Forests is authorized to engage technical specialists in plant protection on yearly contracts. These will not form part of the permanent staff. (*Gazzetta Ufficiale del Regno d'Italia*, Roma, 24 ottobre 1938, anno 79<sup>o</sup>, n. 244, pp. 4426-4427).

\* \* Ministerial Decree of October 13, 1938 authorizes, subject to certain conditions, the shooting and capture of sparrows in the Muratella-Maccarese zone of Rome Province in order to protect crops. (*Ibid.*, 18 ottobre 1938, n. 239, p. 4352).

\* \* By Ministerial Decree of October 19, 1938, the territory of the commune of Giano dell'Umbria has been declared infested with grape phylloxera. (*Ibid.*, 12 novembre 1938, n. 258, p. 4661).

\* \* By three Ministerial Decrees of October 19, 1938, the communes of Padula and Pontecagnano in the Province of Salerno, Capena in the Province of Rome, Montalto delle Marche and Rocca di Fluvione in the Province of Ascoli Piceno have been declared infested with grape phylloxera. (*Ibid.*, 17 novembre 1938, n. 262, p. 4761).

\* \* By Ministerial Decree of December 20, 1938, the application of the exchange duty. at the reduced rate of 0.75 lire per cent., is extended, as from January 15, 1939, to the parasiticide commercially sold as 'Lazio'. (*Ibid.*, 7 gennaio 1939, anno 80<sup>o</sup>, n. 5, p. 82).

\* \* The Ministry of Agriculture and Forests has published the list of the communes in the Kingdom declared to be infested with grape phylloxera or suspected of being so infested on December 31, 1938. (*Bolletino Ufficiale del Ministero dell'Agricoltura e delle Foreste*, Roma, 16 dicembre 1938, anno X, n. 24, pp. 2314-2332)..

[The A. first published plates illustrating different weeds in 1913. A close study of the biology of these competitors of cultivated plants has led the A.

to enlarge this work. This study, now complete, comprises three series, each of 30 plates. The third and last of this series has just been published. Fifty two species of weeds are illustrated, making a total of 138. These are the weeds most commonly found in Europe and North America; some are also spread through South America, Africa and Asia.

As far as possible, the weeds are classified according to a biological standard. The illustrations were made from living species and are in natural colour. The drawings were carried out according to the directions of the A. and under his personal control.

The brochure issued with the coloured plates gives an explication of each illustration; *inter alia*, the name of each weed is given in 12 languages.

The indications on the flowering and fruiting period refer to conditions in central and northern Europe.

# INTERNATIONAL BULLETIN

## OF PLANT PROTECTION

---

### DISCOVERIES AND CURRENT EVENTS \*

#### Italian East Africa: *Locusta migratoria migratorioides* in Eritrea and in Amhara †

Eritrea. During December 1938, further hatchings were noted in the middle zones of Tigrai and the west low-lying plain.

During the first fortnight, swarms were not so numerous as in the preceding months, but towards the end of December they increased in number and size. The zones most seriously affected are still chiefly those of western Tigrai, and to a lesser extent that of Macallé.

A swarm which was reported in the Arafali zone (eastern low-lying plain) and which had commenced egg-laying was entirely destroyed.

In agreement with the General Government of Italian East Africa and with that of the Anglo-Egyptian Sudan, an officer of the Agricultural Bureau of Eritrea was sent to the eastern low-lying plain for the purpose of inspecting the entire coastal zone with a view to ascertaining if there was any possibility of Eritrea being invaded by the desert locust (*Schistocerca gregaria*).

Amhara. The situation is more serious in this region both as regards number of swarms reported and the damage caused to the crops. Here also the species in question is the African migratory locust (*Locusta migratoria migratorioides*).

Most of the districts attacked report that the locusts came from Eritrea across Tacazzé and part of the Anglo-Egyptian Sudan.

As a rule, these swarms have no definite direction; it is noted that they tend to follow a circular movement, and that on settling, they only remain on the ground for brief periods.

Tana is one of the zones most severely attacked, particularly the Gorgorà district.

Control measures. The usual systems of threshing and ditches were employed; when the hoppers had reached the final moulting stage, poison bait gave good results.

\* Under this and the third heading the countries are arranged in French alphabetical order.

† Communication from Dr. LUIGI M. BOLOGNA, Chief of the Agricultural Bureau of Eritrea, Asmara, transmitted to the Institute by the Government of the Colony.

In Tigray, as a result of the active assistance of the people, thousands of sacks of Locusts were collected at night.

In Gasc, in the Alalà area, ploughing was extensively carried out in order to destroy egg-pods.

### Argentine Republic: A Up-to-Date Equipment for Plant Fumigation in the Port of Buenos Aires \*

The installation in the port of Buenos Aires of newly equipped plant disinfection chambers, which was authorized by a Decree of December 9, 1936, is now completed. This important work was carried out by the ' Dirección de Sanidad

General view of plant disinfection equipment

Vegetal' of the Ministry of Agriculture in conjunction with the Architectural Department of the Ministry of Public Works, the result being a thoroughly up-to-date installation comprising all the latest technical refinements.

This new plant is divided into three independent parts and consists of 6 vertical cylindrical autoclaves made of steel, S. M. 44, with a diameter of 3.50

\* Communication from the official correspondent of the Institute, Mr. Juan B. MARCHIONATTO, Agricultural Engineer, Director of 'Sanidad Vegetal', Ministry of Agriculture, Buenos Aires, Argentine Republic.

metres. Each autoclave has a content of 50 cubic metres, which gives a total content of 300 cubic metres for each disinfection. As many as 4 operations can be carried out daily so that, if necessary, a total of 1,200 cubic metres of vegetable matter can be dealt with in one day. Each autoclave is provided with a movable platform for the reception and discharge of the goods, worked by hydraulic pressure. This pressure is regulated by a revolving oil pump which also serves to open and close the cover of the autoclave.

The apparatus is supplied with 3 vacuum pumps which circulate the disinfectant in the autoclaves; 6 powerful ventilators which disperse any vestiges of gas that may remain in the goods after disinfection; and 6 electric carriers of variable gradients for the reception and discharge of the goods. To facilitate the handling of heavy loads there is an electric crane capable of bearing a weight of 5,000 kg.

The disinfection plant is completed by a laboratory fitted with a small autoclave of a content of 2 cubic metres, and various control apparatus.

The disinfectants most generally used are carbon bisulphide and hydrocyanic acid, the latter either in a liquid state or combined with inert matter. In each case it is generated by reaction, with entirely separate installations.

The serious danger of explosion in the case of carbon bisulphide is neutralized by making use of this disinfectant in a vacuum with the addition of carbon dioxide, which renders it inexplusive. When the disinfection process is completed, the gases are expelled from the autoclave by means of compressors, being forced up a chimney of armoured cement, 30 metres high.

The methods adopted in the disinfection plant described above are the latest and most effective known, while its output capacity is the largest in the world.

These chambers are in a specially constructed building covering an area of 1,600 sq. metres and adjoining the premises for the Port Inspection of Plants in the Federal Capital.

### Australia: Aphid Vectors of the Virus of Woodiness Disease of Passion Fruit in New South Wales \*

Woodiness or bullet disease of passion fruit (*Passiflora edulis*) is a virus disease which has been described in detail by the author on completion of mechanical infection experiments in 1928.

Now it has been demonstrated that the woodiness virus may be transmitted by *Myzus persicae*, *Macrosiphum solanifolii* and by two other aphids which belong to the group in which are included *Aphis rumicis*, *A. medicaginis*, etc., and in which there is considerable divergence of opinion as to the synonymy of the species concerned. The two dark aphid vectors of woodiness are characterised and designated as *Aphis* sp. A and *Aphis* sp. B.

A paper of the author in collaboration with Mr. N. S. Noble on this subject is expected to be published in the near future.

\* Communication from the official correspondent of the Institute, Dr. R. J. NOBLE, Biologist, Department of Agriculture, Sydney, New South Wales, Australia.

**Mozambique: Red Locust \***

During October, 1938, swarms of the red locust (*Nomadacris septemfasciata*) were reported in the districts of Tete and Quelimane, Zambezi Province. Some damage was caused to sugar cane and cotton crops in the Quelimane district.

**Southern Rhodesia: Locust Invasion, 1932-38 †**

Monthly Report No. 72. November, 1938.

Flying swarms of the red locust (*Nomadacris septemfasciata*, Serv.) were reported during the month from nineteen districts in the Colony as follows:—

**Mashonaland:—**

Bikita, Charter, Chilimanzi, Darwin, Hartley, Makoni, Marandellas, Mtoko, Mazoe, Melssetter, Victoria, and Umtali.

**Matabeleland:—**

Belingwe, Bulalima-Mangwe, Bulawayo, Chibi, Insiza, and Nyamadhlovu.

A number of swarms have flown south from Matabeleland into the Northern Transvaal and Bechuanaland. Some of the swarms are assuming the mating colouration (turning yellowish) and the ovaries are developing. Two unconfirmed reports were received at the end of the month that egg laying had taken place though it is considered that egg-laying will not become general for another two or three weeks.

Locust birds, storks and kites, have been seen following many of the swarms.

Some damage to gum plantations, wheat, early maize, vegetable gardens and grazing has occurred.

As few reports have been received and many of the swarms are small, the coming hopper outbreak may be similar to last year's, i. e. on a fairly small scale.

**Italian Somaliland: Locusts §**

No locusts were reported in the Colony during December, 1938.

\* Communication from Mr. ALBERTO COUTINHO SARAIVA, Chief of the Section of Entomology, Lourenço Marques, transmitted to the Institute by the 'República Técnica de Agricultura' of Mozambique Colony.

† Communication from Mr. J. K. CHORLEY, Acting Chief Entomologist, Agricultural Laboratory, Department of Agriculture, Salisbury, Southern Rhodesia.

§ Communication from Dr. MARTINO VIDOTTO, Acting Chief of the Agricultural Services of Italian Somaliland, Mogadiscio, transmitted to the Institute by the Government of the Colony.

## VARIOUS QUESTIONS

**Standard Method of Control of the Colorado Beetle (*Leptinotarsa decemlineata*) for the Year 1939.**

The IVth Conference of the International Committee for the mutual study of the control of the Colorado beetle met at Wageningen, the Netherlands on February 2, 3 and 4, 1939, with the participation of the delegates of Germany, England, Belgium, France, the International Institute of Agriculture, Jersey (Channel Islands), Latvia, Luxemburg, the Netherlands, Poland, Switzerland and Czechoslovakia.

The report of the Conference will be published shortly; meanwhile, we reproduce herewith, in view of its topical interest, the text of the standard method of control of the Colorado beetle, adopted by the Conference:—

## I.

For areas with infrequent foci, not attached, the International Committee for the mutual study of the control of the Colorado beetle advocates the following measures:—

## (A) Patrolling.

In a region contaminated or suspected of infestation patrolling should be intensified from the time the soil temperature exceeds 10° C., the optimum temperature for the emerging of the adults being 14-15° C. Such patrolling should be extended to areas cultivated with potatoes, egg-plants, tomatoes and all cultivated or wild Solanaceae, particularly bittersweet. As soon as the fine days begin, patrolling should be made of all the fields in the locality, particularly where the foliage is most developed. Patrolling becomes all the more necessary when the temperature rises to 20° C. or over during several days.

Patrolling is particularly indicated in the direction of the winds prevailing during the hottest hours of the day (10 a. m. to 3 p. m.).

## (B) Discovery of the Insect.

- (1) Immediate collection and destruction on the spot.
- (2) Demarcation of the focus.
- (3) Removal of the haulm which should be carefully collected in the centre of the focus.
- (4) Breaking up of the soil and careful search for insects by sieving the soil.

(5) Treatment of the soil by injection of carbon disulphide (a minimum of 100 grams per sq. metre), or by spraying with benzol or petroleum (5 litres per m<sup>2</sup>).

(6) Distribution of the haulm in the focus.

(7) Repeated treatment of the soil and the haulm with the same products.

Operations (3) to (7) may be substituted by the following:—

(3) Burial of the haulm on the spot at a minimum depth of 60 cm. and spraying with benzol or petroleum.

(4) Sieving of the soil as above.

(5) Treatment of the soil as above.

(8) Immediate treatment of the foliage with an insecticide indicated by the technical Service (such as diplumbic arsenate or calcium arsenate) on all potato fields within a radius of at least 500 metres. Treatment to be repeated, when necessary, two to four weeks later. Eventually, a third treatment.

(9) Inspection and patrolling will be carefully continued after the treatment.

It is recommended to retain the green foliage as late as possible into the autumn and to replant potatoes as early as possible in the spring on the foci to serve as plant-traps.

## II.

When infestation has become widespread, the Committee recommends the application of the following measures:—

Extensive prophylaxis by treating all potato crops with an insecticide of which the effect is immediate and lasts for at least 15 days. These treatments will be carried out in the areas and during the periods where invasion is feared; a poison insecticide should be used: diplumbic arsenate or calcium arsenate.

Spraying should be carried out in increasing quantities up to 700-1200 litres per hectare, according to the extent of foliage and the apparatus employed.

Also, to obtain an even distribution of the substance, products which do not easily form a deposit are necessary. The wash should remain homogeneous throughout the period of spraying, usually carried out by means of an apparatus with preliminary pressure.

As however, treatment cannot be restricted to one chemical compound only, products which do not correspond to the requirements established by the competent official services may be utilized, provided they pass a biological test which proves that they are as effective (immediate and persistent action) as the standard product.

Tests for proving efficacy will be tried out on larvae at the beginning of the fourth stage, and in a sufficiently warm atmosphere (temperature over 15°C during the day).

Curative treatments may be carried out during the course of the season supplementing the preventive measures.

If near market crops or in any other circumstances when the use of an arsenical preparation is not practicable or advisable, contact insecticides (such as rotenone) may be employed. These insecticides should kill off larvae in under twelve hours.

## LEGISLATIVE AND ADMINISTRATIVE MEASURES

**Belgium** \* — By Royal Decree of October 5, 1938, the proprietors, farmers or occupiers, are required to control by every possible means, the diseases (fungi, etc) and pests (insects, spiders, etc.) found on their hop crops.

Ministerial Decree will regulate all measures of control considered effective.

If those concerned are unable to employ effective control measures or if these measures are found insufficient, the burgomaster may order spraying of the hop crops in his commune to be carried out officially.

The Governor has the same authority for the whole province and also for any area in the province he may indicate.

**United States of America.** — For carrying out the purposes of and for expenditures authorized under the public resolution entitled 'Joint resolution making funds available for the control of incipient or emergency outbreaks of insect pests or plant diseases, including grasshoppers [*Acrididae*], Mormon crickets [*Anabrus simplex*], and chinch bugs [*Blissus leucopterus*]', approved on April 6, 1937 [see this *Bulletin*, 1937, No. 8, p. 180], by public resolution approved on March 2, 1938 is appropriated, out of any money in the Treasury not otherwise appropriated, the sum of \$ 2,000,000, to be immediately available and to remain available until June 30, 1939. ([*Public Resolution - No. 81-75th Congress*]. [*Chapter 39-3d Session*], [*H. J. Res. 591*]. [Washington, D. C.], 1938, 1 p.).

\* \* A joint resolution approved on May 9, 1938 amends the aforesaid joint resolution approved on April 6, 1937. ([*Public Resolution - No. 91-75th Congress*]. [*Chapter 192-3d Session*]. [*S. J. Res. 256*], [Washington, D. C.], 1938, 1 p.).

\* \* An Act approved on May 23, 1938 provides for an investigation and report of losses resulting from the campaign for the eradication of the Mediterranean fruit fly [*Ceratitis capitata*] by the Department of Agriculture. ([*Public - No. 535-75th Congress*]. [*Chapter 260-3d Session*]. [*S. 842*], [Washington, D. C.], 1938, 1 p.).

\* \* The revision of the Notice of Quarantine No. 45, on account of the gypsy moth (*Porthetria dispar*) and brown-tail moth (*Nygmia phaeorrhoea* = *Euproctis chrysorrhoea*), and of the rules and regulations (eighth revision) supplemental to the said Notice of Quarantine has been approved on September 28, 1938 and is effective on September 29, 1938.

\* Communication from the official correspondent of the Institute, Prof. F. MARCHAL, Director of the State Phytopathological Station, Gembloux, Belgium.

The principal changes in this revision are (1) the release from regulation of certain towns in Coos County, New Hampshire, and parts of the counties of Caledonia, Essex, Lamoille, and Rutland, Vermont; and (2) the transfer from lightly infested to generally infested area of part of Coos County, parts of the Maine counties of Franklin, Kennebec, Oxford, Penobscot, Somerset, and Waldo, and parts of the Vermont counties of Orange, Windham, and Windsor. The Notice of Quarantine as revised provides for modifications of its restrictions in accordance with facts as to pest risk found by the Chief of the Bureau of Entomology and Plant Quarantine and set forth in administrative instructions. (*B. E. P. Q.-Q.* 45, [Washington, D. C.], 1938, 9 pp.).

**India.** — A press communiqué dated June 23, 1938 informs that the Government of India have decided that the prohibitions and restrictions imposed on the imports of plants, cotton seed, etc., under the Destructive Insects and Pests Act, 1914, and the rules framed thereunder shall be applied to imports from Burma from the 1st August, 1938. (*Agriculture and Live-stock in India*, Delhi, November, 1938, Vol. VIII, Pt. VI, p. 716).

\* \* By Notification No. F. 46-21/38-A., dated July 26, 1938, in rule 6 of the Order published with the Notification No. F. 320/35-A., dated July 20, 1936 [see this *Bulletin*, 1937, No. 5, p. 94], after the words 'Potatoes shall not be imported into British India by sea' the words 'except from Burma' shall be inserted.

The first schedule to the said Order is also modified. (*Ibid.*).

**French Indo-China.** — By Decree of the High Commissioner at Annam, dated July 8, 1938, approved by the Governor General on the 29th of the same month, the boar is added to the list of wild animals and others detrimental to livestock and crops, the destruction and trapping of which is authorized at any period without permit and without any restriction as regards number. (*Journal Officiel de l'Indochine Française*, Hanoi, 10 août 1938, L<sup>ème</sup> année, n° 64, p. 2861).

**Italy.** — With a view to protecting grain crops, Royal Decree-Law No. 1781 of November 24, 1938 authorizes the capture of sparrows during the sowing period and up to the end of March. (*Gazzetta Ufficiale del Regno d'Italia*, Roma, 30 novembre 1938, anno 79°, n. 273, p. 4940).

**Morocco (French Zone of).** — The Vizirial Order of October 24, 1938 (29 chaabane 1357), amending the Vizirial Order of May 9, 1933 (14 moharrem 1352) relating to the issue of health certificates for exported plants, parts of plants or plant products [see this *Bulletin*, 1933, No. 9, p. 207] provides for the issue of these certificates when the laws and regulations of the countries of destination require them. These documents will be issued only when application is made to the regional inspector of the Plant Protection Service. (*Bulletin Officiel*, Rabat, 23 décembre 1938, XXVII<sup>e</sup> année, n°. 1365, p. 1712).

\* \* By Order of the Director of Economic Affairs, dated December 3, 1938, article 1 of the Order of the Director General of Agriculture, Trade and Land Settlement, of June 10, 1932 [see this *Bulletin*, 1932, No. 11, pp. 186-187] enacting measures for the destruction of the fruit fly (*Ceratitis capitata*), is amended as follows:—

‘The persons designated in article 4 of the Vizirial Order of April 18, 1932 [see this *Bulletin*, 1932, No. 7, pp. 112-113] must collect or cause to be collected, at least once a day, the fruits which have fallen to the ground from the trees, shrubs or plants hereinafter named’ (the remainder unchanged). (*Ibid.*, p. 1720).

\* \* An Order of the Director of Economic Affairs, dated December 13, 1938, modifies the area of activity of the ‘Association syndicale de lutte contre le pou rouge [*Chrysomphalus dictyospermi*] de Foucauld’ [see this *Bulletin*, 1937, No. 6, p. 126]. (*Ibid.*, p. 1721).

**Mauritius.** — The Proclamation No. 19 of September 8, 1938 declares that all pineapples planted on any land within the Colony are infested or suspected of being infested with the mealy bug *Pseudococcus brevipes* Ckll.

In consequence the owner or occupier of any such land shall carry out such written orders as may be issued by the Director of Agriculture from time to time for the treatment of the pest and shall uproot and remove or destroy or cause to be uprooted, removed or destroyed, or shall disinfect or cause to be disinfected or otherwise treated any pineapple plants which may be, or may become infested with the pest, if so ordered by him. (*Legal Supplement to the Official Gazette of the Mauritius Gouvernement*, No. 48 of September 10th, 1938).

**New Zealand.** — By Special Order made by the Bruce County Council on September 6, 1938, and published by the Minister of Agriculture on October 19, 1938, broom (*Cytisus scoparius*) and gorse (*Ulex europaeus*) are declared noxious weeds within the said County. (*The New Zealand Gazette*, Wellington, October 27, 1938, Numb. 78, p. 2281).

**Southern Rhodesia.** — By Government Notice No. 456 of September 16, 1938 the Importation of Plants Regulations published in Government Notice No. 462 of August 5, 1932 [see this *Bulletin*, 1933, No. 2, pp. 33-35] have been amended. (*Colony of Southern Rhodesia Government Gazette*, Salisbury, September 16, 1938, Vol. XVI, No. 37, p. 703).

\* \* By Government Notice No. 460 of same date it is notified that the Minister of Agriculture and Lands has fixed the 1st October, 1938, in respect of the year 1938 as the date by which all cotton plants throughout the Colony must have been destroyed in such manner as to prevent their continuing to grow. (*Ibid.*, p. 704).

**Czechoslovakia.** — Decree No. 138 of June 1938 modifies Decree No. 40 of February 25, 1938 [see this *Bulletin*, 1938, No. 6, p. 128] relative to measures for preventing the introduction of the Colorado beetle [*Leptinotarsa decemlineata*]. (*Sammlung der Gesetze und Verordnungen des čechoslovakischen Staates*, Prag, 4. Juli 1938, Jahrg. 1938, 45. Stück, S. 587).

**Tunis.** — A Decree of August 25, 1938 lists the vine-stocks to be used in the preliminary replacing of phylloxera-diseased vines. (*Bulletin de la Direction des Affaires Economiques*, Tunis, 1938, XLII<sup>e</sup> année, 3<sup>e</sup> trimestre 1938, n<sup>o</sup> 174, p. 291-292).

**Union of South Africa.** — Proclamation No. 161 of August 4, 1938 specifies the plants considered noxious in the different regions of the Union. (*The Union of South Africa. Government Gazette*, Pretoria, 12 August, 1938, Vol. CXIII, No. 2556, pp. 434-436).

[ 'Arrossamento striato ' (red stripe) of the plant, probably caused by a virus disease; 'arrossamento maculato ' (red spot of the leaves): in badly affected tissues, a fungus and bacteria are nearly always present; collar rot caused by *Sclerotium delphinii*; root rot (cause as yet undetermined); stem rot caused by a *Fusarium*; dying off of seedlings apparently due to several physical and parasitic factors which acted in combination. Finally, insects, and in particular plant-lice, can cause a type of lesion which may be confused with those produced by the above-mentioned diseases].

### DISCOVERIES AND CURRENT EVENTS \*

#### Italian East Africa: Locust Movements in 1938 †

*Schistocerca gregaria*. This species was not reported in any part of the territory. A temporary patrolling service was set up in the outbreak area of the Red Sea coastal zone.

*Locusta migratoria migratorioides*. During the January-June period, this locust was not seen in the territory.

From July 8 to 12, the first swarms were observed in Eritrea in the Om Ager area (western low-lying plain); the direction taken was southwest to northeast. Other swarms, nearing more and more the sexual maturity stage, followed in the Mareb region and in the bordering areas, coming from the Anglo-Egyptian Sudan and flying eastwards. The other regions of Italian East Africa were not yet invaded.

In August, the locusts were seen in Eritrea still further towards the east, and were found in the western low-lying plain, the tableland, and especially in the Adi Ugri area. Egg-laying and hatchings were reported in Tessenei, Barentù and Agordat. On August 30, the first swarms appeared in Amhara and Gallabat (zone bordering the Sudan), flying from north to south. These swarms were reported at Metemma on the 21st and at Matabià and Quorà a few days later.

During the first twenty days of September, swarms appeared throughout western Eritrea, flying from west to east. In the same period, swarms succeeded frequently in all the territories of Amhara to the west and north-west of Lake Tana. During the last ten days of September, swarms were found, chiefly in Eritrea. Heavy damage was done throughout the low-lying plain and on the western slopes between the 11th and 16th parallel.

On September 17, two swarms from the Sudan appeared in Beni Scianguil territory, directed towards the south. From this period, swarms were frequent, flying from north to south and from northwest to southeast.

All the regions situated to the east of the 39th meridian and to the south of the 9th parallel were still immune.

\* Under this and the next heading the countries are arranged in French alphabetical order.

† Communication from the 'Ispettorato agrario' of the Government of Italian East Africa, Addis Ababa.

In October, hatchings were frequent in the zones of the western low-lying plain, Hamasien and Tigrai. Inspection and control operations were only partially effective in these regions, owing to the extent of the area, the sparse population, etc.

On the uplands of Eritrea very large swarms from the Sudan directed towards the east were still frequent. Some parasites of this locust were reported (*Trombidium* and *Empusa grylli*). Very severe damage was caused in all the zones attacked in Eritrea, to pasturage and crops about to be harvested.

From the first days of October, large swarms appeared in Uolcalt, and during the rest of the month, throughout the northeastern part of Amhara. On October 11, a swarm appeared in Semien and continued its flight towards Addi Arcai. Towards the end of the month invasions were very numerous and caused severe damage in the zones of Bircutan, Dembeà, Ismala Gheorghis and Gubba; the dominant directions were north to south and northwest to southeast.

On October 29, a fresh invasion took place in Asosa, in the Beni Scianguil, the swarms arriving from the north-west, and later in November, three other invasions occurred one after the other.

In November, the centre of attack in Eritrea shifted from the western low-lying plain towards Tigrai. The swarms had no definite direction and did not move far. Some swarms, which had crossed the upland towards the eastern depression of Dancalia, returned towards the west after a few days.

An outbreak area, reported in Gasch, was kept under control.

During November, swarms were reported throughout the territory of Amhara; the zones most severely affected were the environs of Lake Tana, Acefer, Cangià and Engiabarà. The first attacks in Lasta and in Uollo Jeggiù were reported. The most easterly swarms shifted from the Lake Haik zone towards the south along the depression of Combolcià Ciaffà up to Choa.

Egg-laying was reported in the western low-lying plain, in the Gondar zone in the Gurabba plain.

On November 22, numerous swarms invaded the Saio regions and continued southwards. During this period Lekemti was invaded and swarms continued across the Guma, Limmu and Gangerò territories; they appeared, in fact, during the following days in these regions and in Gimma. On December 9, Lekemti was again invaded.

From November 25 to the end of December, Gore was invaded almost daily by swarms mainly from the north and north-west; much of the crops was destroyed.

During December, the swarms were centred in Eritrea; in western Tigrai and Amhara, they shifted to the Uollo territory and centred at Lake Haik. The Uolcalt, Lasta and Gubba territories, however, continued to be invaded and further invasions from the Sudan along the frontier zone took place.

A swarm reported in the Arafali zone (eastern low-lying plain) which had begun egg-laying was destroyed by the control service.

Swarms from Lake Haik appeared in the Debra Sina and Amcober zone on December 7 and 8; some swarms continued their flight towards the eastern low-

lying plain, while the others took a southwesterly direction. During the second decade of December, swarms from the north-east directed towards the south-west were observed in Addis Alem, Ambò and Guder (Choà).

During the last decade of December, the central regions of Gimma were attacked on several occasions by swarms from the north, some of which remained in this zone taking different directions.

Finally, during the last days of December, the first invasions to the east of the lakes, in the Sidama and Arussi areas, were reported; at Dodolà (Gobba) in the Ticcio zone, the swarms came from the south.

In brief, at the end of December, 1938, swarms were observed in all the regions to the west of the 40th meridian; while invasions tended to diminish in gravity in Eritrea and in the north in general, they increased towards the south, tending eastwards. In 1938, no locusts were reported in Italian Somaliland or in eastern and central Harrar.

Control measures are being carried out systematically and with ample material in Eritrea. Poisoned bran was chiefly used, and to a lesser extent, flame throwers for direct control. In the other regions of Italian East Africa, control operations were not sufficiently organized to be effective, being carried out mainly by the natives under supervision.

Systematic locust control and investigation have now been introduced in Italian East Africa. The Agricultural Services are in charge and are assisted by the authorities and the people.

### Palestine: Plant Diseases of Citrus \*

In the following a preliminary list of diseases occurring on citrus plants in Palestine studied at the Division of Plant Pathology of the Agricultural Research Station, Rehovot, from 1923 to 1938 is given. The author was assisted in the determination and collection of these diseases by Dr. M. Chorin and Ing. G. Minz, Assistants of the above mentioned laboratory.

#### CITRUS AURANTIFOLIA SWINGLE VAR. DULCIS. — SWEET LIME.

<i>Alternaria</i> sp.	Leaf spot, black tip, associated with stem spot.
<i>Bacterium citriputeale</i> C. O. Smith.	Blast of twigs.
<i>Colletotrichum gloeosporioides</i> Penz.	Associated with citrus wither-tip and leaf spot.
<i>Deuterophoma tracheiphila</i> Petri.	'Mal secco'.
<i>Diplodia natalensis</i> Pole Evans.	Blight of branches.
<i>Fusarium</i> sp.	Damping off, root rot of trees.
<i>Ganoderma</i> sp.	Wood rot.

\* Communication from the official correspondent of the Institute, Dr. I. REICHERT, Chief Plant Pathologist, Division of Plant Pathology, Agricultural Research Station, Rehovot, Palestine.

<i>Oospora</i> sp.	Fruit rot.
<i>Phoma</i> sp.	Seedling tip rot, on stubs.
<i>Phytophthora citrophthora</i> Smith and Smith.	Gummosis of trunk and collar.
<i>Phyt. citrophthora</i> Smith and Smith. }	Seedling, stem and tip blight.
<i>Phyt. parasitica</i> Dastur. }	Damping off, collar and root rot of trees.
<i>Rhizoctonia bataticola</i> (Taub.) Butl.	Damping off.
<i>R. solani</i> Kühn.	Damping off.
<i>Rhizoctonia</i> sp.	On leaves.
Sooty mould, undet.	
Collar rot, undet.	
Damping off, undet.	
Dry root rot, undet.	
? Ring blotch, undet.	
Albinism, non-parasitic.	On seedlings.
Bench rooting, non-parasitic.	On seedlings.
Chlorosis, undet.	
Frost injury.	On seedlings and trees.
Gum spot, undet.	On leaves.
Hot wind injury.	
Mottle leaf, undet.	
Stem spot, non-parasitic.	Seedlings.
Sun scald.	
Xyloporosis, non-parasitic.	
<i>Cuscuta monogyna</i> Vahl.	On young trees.
Nematodes, undet.	On seeds, on roots.
 <i>CITRUS AURANTIUM</i> L. — SOUR ORANGE.	
<i>Alternaria</i> sp.	Leaf spot, black tip, damping off, associated with stem spot.
<i>Bacterium citriputale</i> C. O. Smith.	Black pit and blast.
<i>Colletotrichum gloeosporioides</i> Penz.	Associated with wither-tip and 'mal secco'; leaf spot.
<i>Diplodia natalensis</i> Pole Evans.	Blight of branches.
<i>Fusarium</i> sp.	Damping off, collar and root rot.
<i>Macrosporium</i> sp.	Leaf spot.
<i>Oospora</i> sp.	Seed rot.
<i>Penicillium</i> sp.	Seed rot.
<i>Phytophthora citrophthora</i> Sm. and Sm. }	Seedling stem and tip blight.
<i>Phyt. parasitica</i> Dastur. }	Brown rot.
<i>Pythium</i> sp.	Damping off.
<i>Rhizoctonia bataticola</i> (Taub.) Butl.	Collar and root rot.
<i>R. solani</i> Kühn.	Damping off, root rot.
<i>Rhizoctonia</i> sp.	Collar rot.

*Sclerotinia* sp.  
 Collar rot, undet.  
 Damping off, undet.  
 Dry root rot, undet.  
 Gummosis, undet.  
 Albinism, non-parasitic.  
 Chlorosis, undet.  
 Frost injury.  
 Gum spot, undet.  
 Hot wind injury.  
 Mottle leaf.  
 Stem spot, non-parasitic.  
 Sun scald.  
*Cuscuta* sp.

Graft rot.  
 Gummosis.

Seedlings.

Seedlings and trees.  
 Leaves.

*CITRUS LIMONIA* OSBECK. - LEMON.

*Alternaria* sp.

*Bacterium citriputale* C. O. Smith.  
*Botryosphaeria ribis* Gros. and Dug.  
*Colletotrichum gloeosporioides* Penz.

Associated with wither-tip; leaf spot,  
 black fruit rot.

Blast and black pit.

Blight of branches.

Associated with wither-tip and 'mal  
 secco'; leaf spot, anthracnose, fruit  
 rot.

'Mal secco'.

Blight of branches.

Blight of branches.

Stem, collar and root rot; twig blight,  
 gummosis, fruit rot.

Associated with *Colletotrichum* fruit  
 rot.

Brown rot of fruit.

Root rot.

Twig dry rot.

Petioles.

Fruit.

Twigs.

Fruit.

*Oospora* sp.

*Phytophthora* sp.

*Rhizoctonia bataticola* (Taub.) Butl.

*Sclerotinia sclerotiorum* (Lib.) Mass.

Breakdown spot, non-parasitic.

Brown twig spot, non-parasitic.

Frost injury.

Gummosis, non-parasitic.

Gum spot, undet.

Hail spot.

Leaf spot, non-parasitic.

Leaf scorch, non-parasitic.

Leaf yellowing, non-parasitic.

Sun scald.

Wither-tip, undet.

Wind injury.

*Cuscuta monogyna* Vahl.

Branches.

Twigs.

*CITRUS MAXIMA* (BURM.) MERRILL. — PUMMELO.

*Sclerotinia minor* Jagger. Fruit rot.  
 Fruit cracking, non-parasitic.  
 Leaf roll, non-parasitic.

*CITRUS MEDICA* L. — CITRON (ETHROG).

*Alternaria* sp. Associated with blight.  
*Bacterium citriputale* C. O. Smith. Blast.  
*Colletotrichum gloeosporioides* Penz. Anthracnose, fruit rot.  
*Deuterophoma tracheiphila* Petri. 'Mal secco'.  
*Diplodia natalensis* Pole Evans. Blight of branches.  
*Fusarium* sp. Stem rot (on sweet lemon).  
*Penicillium* sp. Fruit rot.  
 Breakdown (Nuksan), non-parasitic. Fruit.  
 Endoxerosis, non-parasitic. Internal decline.  
 Frost injury.  
 Leaf yellowing, non-parasitic.  
 Little leaf, undet.  
 ? Ring blotch.

*CITRUS NOBILIS* LOUR. VAR. *DELICIOSA* SWINGLE. — MANDARIN.

*Bacterium citriputale* C. O. Smith. Blast.  
*Colletotrichum gloeosporioides* Penz. Associated with citrus blast.  
*Penicillium digitatum* Sacc. Green mould on fruit.  
*Phomopsis* sp. Blight.  
*Pleospora* sp. Fruit rot.  
 Black tip, non-parasitic.  
 Chlorosis, non-parasitic.  
 Fruit cracking, non-parasitic.  
 Leaf scorch, non-parasitic.  
 Sun scald.  
 Wind injury.

*CITRUS PARADISI* MACF. — GRAPEFRUIT.

*Alternaria* sp.  
*Bacterium citriputale* C. O. Smith. Blast of twigs.  
*Botryosphaeria ribis* Gros. and Dug. Blight of branches.  
*Botrytis* sp. Grey mould of fruits.  
*Cladosporium* sp. Sooty mould.  
*Colletotrichum gloeosporioides* Penz. Associated with wither-tip; leaf spot.  
*Didymella* sp. Leaf spot.  
*Diplodia natalensis* Pole Evans. Blight of branches.  
*Fusarium* sp. Stem, collar and root rot, fruit rot, gummosis.

<i>Leptothyrium pomi</i> (Mont. and Fr.) Sacc.	Fly speck on fruits.
<i>Penicillium digitatum</i> Sacc.	Green mould of fruits.
<i>Phytophthora citrophthora</i> Sm. and Sm.	Brown rot of fruits.
<i>Phyt. parasitica</i> Dastur.	Brown rot of fruits. Collar rot (on sour orange). Fruit rot. Leaf spot.
<i>Phytophthora</i> sp.	Root rot (on sour orange). Collar and root rot (on sour orange). Twig dry rot.
<i>Pleospora</i> sp.	Fruit, leaves.
<i>Rhizoctonia bataticola</i> (Taub.) Butl.	Leaves.
<i>R. solani</i> Kühn.	On sour orange and sweet lemon.
<i>Sclerotinia sclerotiorum</i> (Lib.) Mass.	Trunk, twigs.

<i>Rhizoctonia solani</i> Kühn.	Damping off.

**Poland: The Beet Weevil \***

The beet weevil, *Cleonus* (*Bothynoderes*) *punctiventris* Germ, recently reported in Poland, has already become a menace to the sugar industry and beet-growers in the county of Volhynia.

The appearance of some adult weevils in 1931 seemed only to have a scientific interest, but these insects have since increased to such an extent that in 1936, they were to be found in 16 localities. In the neighbourhood of Szpanów, the average number of adult insects per ha. amounted to 3000. In 1937, *B. punctiventris* was reported in 56 localities of 6 districts in Volhynia.

\* Communication from the official correspondent of the Institute, Professor STANISŁAW MIKIEWICZ, Chief of the Department of Entomology, State Institute for Agricultural Research, Puławy, Poland.

\* Mon. 4 Ingl.

As a control measure, protective ditches are dug around the beet fields, and the adult weevils are collected. Insecticides have not yet been tried.

Biological studies on the behaviour of the insect in Poland have been undertaken at the Volhynia Plant Protection Station at Luck.

### Southern Rhodesia: Locust Invasion, 1932-38 \*

Monthly Report No. 73. December, 1938.

Flying swarms of the red locust (*Nomadacris septemfasciata*, Serv.), some described as large and all either fully matured or approaching maturity, were reported during the month from seventeen districts in the Colony as follows:—

**Mashonaland:** Charter, Chibi, Darwin, Hartley, Lomagundi, Makoni, Mazoe, Mtoko, Melssetter, Nganga, Umtali and Victoria.

**Matabeleland:** Belingwe, Bulawayo, Bulalima-Mangwe, Gwanda and Insiza.

Egg-laying, which commenced at the end of November, was reported from six districts in Mashonaland, namely: Chibi, Darwin, Hartley, Melssetter, Mtoko, and Umtali, and one district in Matabeleland, namely, Belingwe. Egg-laying in the northern portion of the Darwin District has occurred on a large scale.

The first hopper swarms were reported from the Umtali District on the 19th instant, and from the Mtoko District on the 30th.

It would appear that the swarms invading the eastern districts from Portuguese East Africa were more advanced than the swarms originating in Southern Rhodesia.

Locust birds have been seen following many of the flying swarms.

Little damage has been reported generally, although 100 acres of maize was destroyed on one farm.

## LEGISLATIVE AND ADMINISTRATIVE MEASURES

**Algeria.** — An Order of November 8, 1938 modifies the Order of September 12, 1932 regarding the organization of the Service for plant protection and phytopathological control. (*Journal Officiel de l'Algérie*, Alger, 25 novembre 1938, XII<sup>e</sup> année, n<sup>o</sup> 47, p. 2090).

**Germany.** — By Ministerial Order of November 7, 1938 amending the Decrees of March 28 and September 30, 1932 [see this *Bulletin*, 1929, No. 6, p. 83, and 1932, No. 12, p. 205] the purpose of which was to prevent the introduction of the carnation leaf-roller [*Tortrix promubana*], the importation of

\* Communication from Mr. J. K. CHORLEY, Acting Chief Entomologist, Agricultural Laboratory, Department of Agriculture, Salisbury, Southern Rhodesia.

carnations (cut flowers) is allowed as from November 15, 1938 instead of from November 30. (*Nachrichtenblatt für den Deutschen Pflanzenschutzdienst*, Berlin, Anfang Dezember 1938, 18. Jahrg., Nr. 12, S. 109-110).

**Australia (Western Australia).** — On December 6, 1938 notice is given that Indian hemp (*Cannabis sativa*) has been declared a noxious weed throughout the State and that *Watsonia angusta*, *W. meriana* and *Antholyza aethiopica* have been declared noxious weeds within the boundaries of the Gingin Road Board District. (*Government Gazette of Western Australia*, Perth, December 3, 1938, No. 58, p. 2118).

\* \* \* On December 22, 1938 it has been published that Arum lily (*Zantedeschia* [*Richardia*] *aethiopica*) has been declared a noxious weed within the boundaries of the Capel Road Board District. (*Ibid.*, December 23, 1938, No. 61, p. 2191).

**Cyprus.** — By Order No. 197 of October 13, 1938, which may be cited as the Plant Diseases (*Icerya purchasi*) Order, 1938, within any area declared to be infested by this scale insect the following provisions shall have effect:—

(a) All or any trees or plants whatsoever within any such area as the Director of Agriculture may require shall be fumigated, sprayed, destroyed or otherwise treated as the Director of Agriculture shall require.

(b) No trees or plants or any part thereof shall be removed from any such area without the written permission of the Director of Agriculture previously obtained and such permission shall be subject to such conditions as he may require.

(c) Any person instructed by the Director of Agriculture may enter any land, garden, yard or any other place within any such area and may carry out such inspection and examination of any trees, plants any parts thereof and carry out such treatment of the same as may be required by the Director of Agriculture as in paragraph (a) hereof provided. (*Supplement No. 3 to the Cyprus Gazette No. 2679 of 14th October, 1938. Subsidiary Legislation*, Nicosia, 1938, pp. 480-481).

\* \* \* By Declaration No. 198 of same date the area described in the joint Schedule is declared to be a place infested with *I. purchasi*. (*Ibid.*, p. 481).

**Colombia.** — Law No. 203 of November 30, 1938 relative to plant protection, the import, export and transport of plants and other plant products, trade control and the use of insecticides, fungicides and the necessary apparatus, establishes the penalties for infractions of Government measures and also the quotas to be paid by the Government and growers towards the expenses incurred in the control of plant diseases and pests. (*Diario Oficial*, Bogotá, 1º de diciembre de 1938, año LXXIV, núm. 23938, pág. 595).

**Dominican Republic.** — In order to prevent the introduction of *Cercospora musae*, causal agent of Sigatoka disease now recorded in Central America, Queensland, Java, Malaya and Fiji, and also the disease, not yet determined, attacking the banana in Haiti, Decree No. 74 of November 7, 1938 prohibits import into the Dominican Republic of living or dead plant matter and *Musa* spp. from the above-mentioned countries. (*Revista de Agricultura*, San Cristóbal, Prov. Trujillo, República Dominicana, noviembre de 1938, vol. XXIX, núm. 110, pág. 556).

**Egypt.** — By Order of December 20, 1938, *Pulvinaria psidii* is declared a pest harmful to fruit trees.

The Governorship of Cairo, its surroundings and the town of Guizeh, have been declared infested by this scale insect.

It is prohibited to transport, by any means whatever, *Ficus* or guava plants and any parts or fruits of these from the infested zone to any other locality. (*Journal Officiel du Gouvernement Egyptien*, Le Caire, 26 décembre 1938, 65<sup>ème</sup> année, n° 141, p. 3).

\* \* By another Order of the same date, *Aulacaspis rosae* has also been declared a pest of fruit trees.

The Governorships of Alexandria and of Port Said have been declared infested by this scale insect.

It is prohibited to transport, by any means whatever, from the infested zone to any other locality, plants of the Rosaceae family, liable to attack by *A. rosae* (apple, pear, quince, plum, apricot, cherry, almond and peach trees, strawberry plants, rose bushes, etc.). The sale or offer for sale of plants, parts of plants or fruits, infested by this insect, is also prohibited. (*Ibid.*, p. 4).

**United States of America.** — Amendment No. 5 to revised rules and regulations supplemental to Notice of Quarantine No. 52 on account of the pink bollworm of cotton [*Pectinophora (Platyedra) gossypiella*] adds to the lightly infested area that part of Pinal County in Arizona not heretofore within the regulated area, all of Maricopa County in Arizona, and the Texas counties of Brooks, Jim Wells, Kenedy, Kleberg, and Nueces. This action is taken with respect to all counties, except Kenedy, owing to the recent finding of light infestations of the pink bollworm. Kenedy County is included in the regulated area because there are no facilities in that county for ginning the small acreage of cotton grown therein which is normally ginned in the regulated area.

This amendment of regulation 3 was approved on November 15, 1938 and became effective on November 17, 1938. (*B. E. P. Q.* - Q. 52, [Washington, D. C.], 1938, 2 pp.).

**Guadeloupe.** — A Decree of the President of the French Republic dated November 9, 1938, enacts that, with a view to preventing the spread in Guadeloupe of banana diseases and pests, it is prohibited:—

(1) To utilize banana waste as packing material for transport of commodities within the Colony;

(2) To remove, transport or sell banana plants or parts of plants coming from infested plantations or regions.

Banana plantations are placed under the supervision of the Agricultural Service. For this purpose, every planter is required to declare his plantation in the place where he is resident.

Where a plantation is attacked by parasites or infected by a disease of some gravity, a special declaration must be made to the Agricultural Service which will make the necessary investigations and indicate the measures to be taken.

Owners of plantations infected by a cryptogamic disease or attacked by insects are required to apply the treatments prescribed by the Agricultural Service. The officers of this Service will supervise these applications.

On plantations seriously attacked, the destruction of the plants on the spot, by burning, shall be effected by the owners, or at their expense, on the request of the Agricultural Service.

For the laying out of new plantations, application must be made to the Government of the Colony. Permission will be given only on the reasoned recommendation of the Agricultural Service. (*Journal officiel de la République française*, Paris, 18 novembre 1938, LXX<sup>e</sup> année, n<sup>o</sup> 270, p. 13078).

**Italy.** — The Royal Decree-Law No. 2205 of July 27, 1938 relative to the organisation and operation of the Royal Agronomic Institute for Italian Africa (formerly the Italian Colonial Agricultural Institute, Florence) specifies that this Institute is the scientific and technical department of the Ministry of Italian Africa for agricultural research and experimentation.

The said Institute is required, *inter alia*, to study the plant and animal pests of crops; for this purpose the Institute has at its disposal a laboratory for agricultural entomology and another for plant pathology. (*Gazzetta Ufficiale del Regno d'Italia*, Roma, 28 febbraio 1939, anno 80<sup>o</sup>, n. 49, pp. 1067-1071).

\* \* By Ministerial Decree of November 23, 1938, the application of the exchange duty, at the reduced rate of 0.75 lire per cent., is extended, as from December, 15, 1938, to the parasiticide commercially sold as 'Polvere anticrittogamica al 16 per cento di rame'. (*Ibid.*, 26 dicembre 1938, anno 79<sup>o</sup>, n. 294, p. 5277).

\* \* By Ministerial Decree of December 5, 1938 this exchange duty is applied, as from January 1, 1939, to the product commercially sold as 'Solfocuprica'. (*Ibid.*, p. 5278).

\* \* By Ministerial Decree of December 19, 1938, a competition has been opened, based on tests and qualifications, for a bursary for advanced study in phytopathology with particular reference to citrus cultivation, at the Royal Observatory for Plant Diseases attached to the Royal Station for Fruit and Citrus Crops, Acireale. (*Ibid.*, 19 gennaio 1939, n. 15, pp. 290-291).

\* \* The Ministerial Decree of December 26, 1938 which fixes the special rules for the export of lettuces (cabbage and roman) and of endives (including curled variety) requires, *inter alia*, that these salads shall be free from attacks of parasites and frost damage. (*Ibid.*, 2 gennaio 1939, n. 1, pp. 4-7).

**Kenya.** — By Government Notice No. 851 of November 21, 1938, the importation into the Colony and Protectorate of Kenya of any rooting medium for plants which consists either wholly or in part of soil, whether or not it is attached to any plant, is prohibited.

No consignment of fruit grown in countries other than Zanzibar, Tanganyika Territory and Uganda, shall be permitted to enter the Colony unless accompanied by a certificate signed by an officer of the exporting country duly authorized by the Government of that country, to the effect that a percentage (to be stated) of the packages in the consignment has been examined by him and has been found to be free from insect pests.

The Schedule to Government Notice No. 688 of September 2, 1937 [see this *Bulletin*, 1938, No. 4, pp. 82-83] is amended by adding at the end thereof the following:— Barberry [*Berberis vulgaris*] and buckthorn [*Rhamnus cathartica*]. (*Colony and Protectorate of Kenya. Official Gazette Supplement. Proclamations, Rules and Regulations, No. 42. Supplement No. 46, Nairobi, November 29, 1938, Vol. XL, No. 57, p. 373*).

**Morocco (French Zone of).** — Decree of November 15, 1938 authorizes the destruction of boars which have been causing severe damage to the crops in the territory of the Ouezzane Circle. (*Bulletin Officiel*, Rabat, 25 novembre 1938, XXVII<sup>e</sup> année, n<sup>o</sup> 1361, p. 1605).

\* \* By Vizirial Decree of December 24, 1938 (2 kaada 1357), the Vizirial Decree of March 17, 1936 (23 hija 1354) listing the plant parasites for which syndical control associations may be established [see this *Bulletin*, 1936, No. 8, p. 179] has been supplemented as follows:—

.....  
Mediterranean fruit fly (*Ceratitidis capitata*, Wied.). (*Ibid.*, 27 janvier 1939, XXVII<sup>e</sup> année, n<sup>o</sup> 1370, p. 104).

\* \* An Order of December 30, 1938 authorizes the destruction of rabbits causing serious damage in the Rabat area and in Port-Lyautey territory. (*Ibid.*, 13 janvier 1939, n<sup>o</sup> 1368, p. 37).

\* \* An Order of December 31, 1938 authorizes the establishment of a syndical association for the control of plant parasites called the 'Association syndicale de lutte contre les parasites des plantes de Sidi-Slimane'. (*Ibid.*).

**New Zealand.** — By Resolution passed by the Kaitieke County Council on November 14, 1938, and published by the Minister of Agriculture on November

24, 1938, the said Country Council has assumed responsibility for the administration of the Noxious Weeds Act, 1928 as from November 14, 1938. (*The New Zealand Gazette*, Wellington, December, 1, 1938, Numb. 85, p. 2479).

**Rumania.** — Order No. 300.216 of November 17, 1938 authorizes the transport through Rumania of all species of trees, shrubs, plants, cuttings, vines and other root plants, and also potatoes, beans, peas, lentils and fodder seed, provided that consignments are accompanied by a certificate testifying to condition and origin, granted by a State establishment recognized by the Rumanian Government. (*Monitorul Oficial*, Bucuresți, la 23 Noemvrie 1938, anul XVI, Nr. 273, pag. 5601).

**Tunis.** — By Decree of November 17, 1938, owners or occupiers of establishments such as nurseries, gardens or other horticultural land engaged regularly in the propagation of, or trade in plants, are required to destroy any parasitic foci appearing on their parent plants, beds, stocks, young plants whether grafted or not, windbreaks, etc.

On such establishments, whatever the condition of the plants, the following treatments are compulsory:—

(1) For all deciduous fruit trees:—

(a) Winter spraying, by means of a sprayer with a minimum pressure of 8 kg. to the square centimetre, with one of the following materials: organic colouring substances, anthracenic oils, white oils, polysulphides.

This treatment must be effected by February 15 at latest.

(b) Spraying carried out at the time of budding with copper mixture, containing 0.50 per cent. of copper metal.

(2) In addition to the above treatment, almond, apricot, peach, plum and cherry trees must be given the following treatments:—

Spraying effected in autumn, when the leaves fall, with a copper mixture containing 0.75 per cent. of copper metal.

This treatment must be effected by December 20 at latest.

Parasiticides other than those enumerated may be used if a permit is obtained from the Director of Economic Affairs.

Plants ascertained in the course of the sanitary inspection to be infested shall be at once destroyed. In default, the destruction will be effected by the administrative authority, without prejudice to the infliction of the penalties provided. (*Journal Officiel Tunisien*, Tunis, 6 décembre 1938, 56<sup>e</sup> année, n<sup>o</sup> 97, p. 1575).

**South Africa (Union of).** — By Proclamation No. 265 of December 1, 1938, the removal of any plant or portion of a plant belonging to any species of *Opuntia* (prickly pear) from the districts where certain insects, namely *Cactoblastis cactorum*, are being used for the biological control of the aforesaid prickly pears, is prohibited except under authority of the Minister of Agriculture and Forestry. (*The Union of South Africa Government Gazette*, Pretoria, 9 December 1938, Vol. CXIV, No. 2590, p. 830).

## OF PLANT PROTECTION

---

### DISCOVERIES AND CURRENT EVENTS \*

#### Eritrea and Amhara: Locust Movements †

During January, 1939 an expert of the Agricultural Bureau of Eritrea made a caravan tour of the low-lying eastern plain from Ras Casar to Zula without noting any desert locusts (*Schistocerca gregaria*) or African migratory locusts (*Locusta migratoria migratorioides*). Observers were stationed at Mersa Taclai, Scheeb and at Zula.

Egg-pods and hoppers of *L. migratoria migratorioides*, however, were reported in the territories of the Commissariats of western Tigrai, in the western low-lying plain and in the Commissariat of Macallè, towards the end of the month.

Swarms were less numerous than in the previous months, though towards the end of January they increased somewhat disquietingly in certain areas. In the western low-lying plain of western Tigrai, fairly large swarms, which however, never followed any definite direction, were frequently reported.

In comparison with December, 1938, the situation in Amhara had improved considerably.

Small swarms of *L. migratoria migratorioides* were still noted in the Commissariat of Gondar, in the basin of Lake Tana and in Curamba plain. No egg-pods were found.

The ordinary control measures were continued: threshing, ditches and poison bait.

A method which has given good results in the newly annexed territories is collection of the adults in the morning, when they are still inactive from the cold of the previous night.

In some areas where the land allowed of it, ploughing was carried out to unearth the eggs.

#### Estonia: Plant Diseases New to the Country §

*Uromyces sanguinea* Magn. Reported for the first time on November 10, 1934 in Raadi Park, near Tartu, on the leaves of *Mahonia aquifolium*. This disease had already appeared in Latvia and in Finland some years previously.

*Neofabraea corticola* (Edgert) C. A. J. First observed in 1935 on a trunk of *Pyrus malus*. Now fairly widely spread.

\* Under this and the next heading the countries are arranged in French alphabetical order.

† Communication from Dr. LUIGI M. BOLOGNA, Chief of the Agricultural Bureau of Eritrea, Asmara, transmitted to the Institute by the Government of the Colony.

§ Communication from Professor E. I. EPIK, Director of the University Phytopathological Station, Tartu, Estonia.

*Oidium euonymi-japonici* (Arc.) Sacc. Introduced with plants of *Euonymus japonicus* from Central Europe, was first noted in 1935 at Paide; is now found in certain greenhouses.

*Uncinula necator* (Schw.) Burr. Introduced from Germany with plants of *Vitis vinifera*, it was first reported in 1936. The disease was only noted in one locality, and was stamped out by means of careful disinfection.

*Botrytis paeoniae* Oudem. Introduced from western Europe with some peony plants, was first reported in 1932. The disease is now to be found in certain regions.

*Botrytis tulipae* (Lib.) Lindb. Introduced from western Europe with tulip bulbs, it was first reported in 1937. At present the disease is of infrequent occurrence.

*Fusarium conglomerans* Wr. var. *callistephi* Beach. Was only reported in the summer of 1933, but probably had already been in the country for some time.

*Pestalotia lupini* Sor. Noted for the first time in 1935 in crops of *Lupinus perennis*.

*Phyllosticta sojaecola* Mass. Reported in 1935 on the leaves of *Glycine soja*.

### Italy: The 'Fetola' or Yellow Spot of Citrus in Sicily\*

During the last decade of December, 1938 when I was at Adrano in the province of Catania, several growers asked me about a serious disease of the orange, called here as in other parts of Sicily, 'fetola'.

This disease has only been observed in recent years in Adrano and in the other citrus areas of the Simeto Valley (localities of Aragona, Canalotto, Ruggeri, Carcaci, Cugno di Carcaci, Miraglia, Cavallera, Mandarano, Schittino, Marotta, Don Carlo, Ciappa, etc.), but it has developed to an alarming extent in the last two years. It is estimated that in some of the above-mentioned localities (e. g., Aragona) a fifth or even as much as a quarter of the present season's orange production is spoilt through 'fetola' or yellow spot. In view of the present prices obtained for oranges, this is a heavy loss.

The value of the fruits is appreciably reduced, as they cannot be classed as first grade oranges.

The skins of oranges attacked by 'fetola' show spots round in shape if isolated and more or less irregular if joined, slightly concave. The number of these spots varies: from only a few to 40 or even more per fruit. Each spot may spread over a surface of a few millimetres to several centimetres (fig. 1). The spots on the epicarp have a dotted aspect; this is due to the oil-bearing glands which are not attacked. When the air penetrates into the interglandular tissue, the oil therein dries up, the tissue turns a sulphur yellow colour and the spots have a reticulated appearance (fig. 2).

This disease generally appears in September and becomes more decided during the following months.

The disease differs from that known as 'petecchia' as the oranges attacked by the latter show brownish and more concave spots.

\* Communication from Professor GIUSEPPE RUSSO, Laboratory of Agricultural Entomology of the University of Naples, Portici, Italy.

A disease similar to 'fetola' has been known for several years in California where it is called fruit spotting. It was recently shown that this is due to

FIG. 1.

the attack of a small jassid, *Empoasca fabae*. It is probable that the 'fetola' in Sicily is also due to insects belonging to the same family (genus *Empoasca*

FIG. 2.

or one similar). This would confirm the opinion of some citrus-growers that the 'fetola' is more extensive in the zones where cotton is cultivated. Cotton is a host plant of Jassids, which can easily change to citrus.

The subject is an important one, and a careful biological study of both the 'fetola' and cotton insects, with a view to obtaining an effective method of control, would be useful.

In California, to control the insects causing fruit spotting, spraying with the following mixture is now recommended:—

Calcium hydrate . . . . .	6 kg.	(150 lb.)
Zinc sulphate . . . . .	950 grams	(24 lb.)
Blood albumin . . . . .	42 cc.	(1 pint)
Water . . . . .	100 litres	(300 gallons)

This mixture exerts a repellent action. In West Indies and in Italian Somaliland, I obtained good results in controlling certain species of *Empoasca* by spraying the attacked plants with a 1 per cent. Bordeaux mixture, which also has a repellent action.

In Italy, a preparation similar to the American mixture could be tried, as also lime-sulphur wash (4-5 per cent.) mixed with sodium or lime caseinate (50 grams in 100 litres); the latter substance increases the adhesiveness of the liquid. Dusting the plants with sulphur mixed with pyrethrum or tobacco powder should also be tried. Treatment with powder or liquid preparations should begin several weeks before the first attack of the insects on the fruits.

### Poland: Organization of the Plant Protection Service \*

Plant protection in Poland is based on the activities of the 13 plant protection Stations attached to the Chambers of Agriculture. In these Stations is concentrated all the practical work done in this sphere in the various counties, in accordance with measures taken by the Government, administrative authorities and various social organizations. These Stations work in close collaboration with agricultural and horticultural experiment Stations, seed-testing Stations and schools of agriculture. Plant protection Stations are authorized to issue sanitary certificates for exports, signed by the directors of the Stations in their capacity of plant protection inspectors.

The Stations are in general maintained and controlled by the Ministry of Agriculture and Agrarian Reform, the Plant Protection Section of the Government Institute for Agricultural Research at Pulawy being the central service. Among the most important duties of this Section are the planning of control methods, the preparation of general reports on the work of the Plant Protection Service, the direction of propaganda and the control of the means of carrying on the campaign.

\* Communication from Dr. J. RUSZKOWSKI, Director of the Plant Protection Section, Government Institute for Agricultural Research, Pulawy, Poland.

An annual meeting is held at the Ministry of Agriculture attended by representatives of the institutions engaged in plant protection or interested in the progress accomplished, and reports on this subject are presented. Moreover, the Pulawy Plant Protection Section invites the entire staff of the Service to its two annual meetings, one of which is held during the winter, in the capital, and the other during the summer, at one of the plant protection Stations, all Stations being visited in turn.

Two sections of the Central Institute are specially devoted to scientific work, namely, those for plant diseases and pests.

The Institute publishes two periodicals, one of which deals with the scientific work mentioned above and the other with practical matters. The latter is also the organ of the Plant Protection Service.

### **Southern Rhodesia: Locust Invasion, 1932-39 \***

Monthly Report No. 74. January, 1939.

Winged swarms of the red locust (*Nomadacris septemfasciata*, Serv.) have been reported from the following districts during the month of January 1939, namely:—Lomagundi, Darwin, Mazoe, Mtoko, Umtali, Bikita, Victoria, Ndanga, Gwanda, and Belingwe.

All the swarms were in breeding condition and practically all were engaged in egg-laying.

Hoppers have appeared in the districts of Lomagundi, Darwin, Mrewa, Inyanga, Melsetter (Chipinga), Bikita, Charter, Ndanga, Chibi, and Belingwe.

The hoppers are being destroyed in all accessible localities.

The position generally appears to be very similar to that obtaining during January, 1938, although rather fewer reports of locusts have been received. Hatchings appear to have commenced nearly two weeks earlier during the present season compared with last year.

### **Italian Somaliland: Locusts †**

No locusts were reported in the Colony during January, February and March, 1939.

\* Communication from the official correspondent of the Institute, Mr. RUPERT W. JACK, F. E. S., Chief Entomologist, Agricultural Laboratory, Department of Agriculture, Salisbury, Southern Rhodesia.

† Communication from Dr. LUIGI BOZZI, Chief of the Agricultural Services of Italian Somaliland, Mogadiscio, transmitted to the Institute by the Government of the Colony.

\* Mon. 5 *Ingl.*

## LEGISLATIVE AND ADMINISTRATIVE MEASURES

Germany. — A Law of October 1, 1938 relative to carrier-pigeons prohibits the shooting of these birds. Landowners are no longer allowed to capture pigeons found on their property during the sowing period. (*Nachrichtenblatt für den Deutschen Pflanzenschutzdienst*, Berlin, Anfang März 1939, 19. Jahrg., Nr. 3, S. 22).

\*\*\* A Decree of October 15, 1938 relative to the damage caused by wild rabbits prescribes that every effort should be made to eliminate these animals in fenced-in areas.

As many landowners have complained that the game law and police measures in force prohibit them from shooting the rabbits, it is suggested that the competent authorities should select trustworthy persons specially for the purpose of shooting the rabbits; a limited district will be assigned to each. Proprietors sustaining losses through rabbits may apply to these official huntsmen, who will be compensated for their expenses keeping the game. (*Amtliche Pflanzen-schutzbestimmungen*, Berlin, 1. Februar 1939, Bd. XI, Nr. 1, S. 18-19).

\*\*\* By Circular of January 9, 1939, the Minister of Agriculture instructs that the number of potato varieties non-resistant to wart disease [*Synchytrium endobioticum*] still allowed for planting must be reduced to a minimum until finally eliminated in 1941. (*Ibid.*, S. 1-2).

\*\*\* An Ordinance of January 10, 1939 issued by the General Potato Union modifies the regulations relative to the trade in potatoes established by Ordinance No. 8 of June 20, 1935 [see this *Bulletin*, 1935, No. 9, pp. 203-204]. (*Ibid.*, S. 6-13).

\*\*\* An Ordinance of January 10, 1939 by the deputy of the Minister of Agriculture dealing with questions referring to seeds, revises the regulations relative to trade in seed potatoes. The regulations fixed by this Ordinance supplement those already laid down in respect to trade in potatoes (see below). The provisions are mostly of a phytosanitary nature.

A distinction is made between (a) choice potatoes ('Hochzucht'); (b) certified seed potatoes ('Anerkannter Nachbau') and (c) ordinary commercial potatoes ('Handelsaat').

There are detailed provisions regarding quality. Account is taken of certain factors affecting quality: earth contained in consignments, slight defects, infraction of the regulations, serious injuries, diseases, damage caused by rot, moisture and frost, proportion of tubers not conforming to standard, wart disease. A table indicates the degrees of deterioration which the purchaser must accept and

the percentage of tubers below standard which give the right to a reduction in price or return of the consignment.

The diameter of round potatoes should not be lower than 3.4 cm. nor greater than 7 cm.; for oblong varieties, the diameter ranges from a minimum of 4 cm. to a maximum of 8 cm.

Among slight defects are included: rust marks, inner woody layers, green tubers, slight wart disease, cracked skin, etc.

Injuries produced by animals or any other cause which may reduce germinative power are considered as serious defects.

Potato plants for export should be inspected for both phytosanitary condition and quality, taking into account the regulations in force in the importing country. (*Ibid.*, S. 14-17).

**Germany (Thuringia).** — By Decree of January 24, 1939 modifying the Decree of March 18, 1935 relative to protecting newly sown fields against pigeons [see this *Bulletin*, 1935, No. 6, p. 133] proprietors of pigeons are required to prevent their birds from going into newly sown fields and gardens during the spring sowing period. This protection period is limited to four weeks in spring and four weeks in autumn. The period may be extended, however, to six weeks or even longer, if authorized by the Minister of Agriculture.

Landowners are allowed to capture any pigeons found on their property during the above-mentioned period. (*Ämtliche Pflanzenschutzbestimmungen*, Berlin, 1. Februar 1939, Bd. XI, Nr. 1, S. 20).

\* \* An Ordinance of February 10, 1939 establishes that from this date the police authorities may no longer issue permits for shooting sparrows.

It is suggested that sparrows be controlled by destroying their nests and using the Schwing trap. (*Nachrichtenblatt für den Deutschen Pflanzenschutzdienst*, Berlin, Anfang März 1939, 19. Jahrg., Nr. 3 S. 22).

**Chile.** — The bean weevil (*Bruchus obsoletus*) having been found in the commune of Limache, Department of Valparaiso, Decree No. 811 of December 31, 1938 declares infested the whole of the zone where this pest was noted and makes control measures compulsory. (*Diario Oficial de la República de Chile*, Santiago, 20 de enero de 1939, año XLII, núm. 18.271, pag. 191).

**United States of America.** — The Notice of Quarantine No. 72 and the regulations supplemental hereto, approved on December 14, 1938 and effective on January 15, 1939, contains measures for preventing the spread of dangerous infestations of the white-fringed beetle (*Naupactus leucoloma*) and a closely related species of *Naupactus* in the States of Alabama, Florida, Louisiana, and Mississippi. (*B. E. P. Q.* — Q. 72, [Washington, D. C.], 1939, 5 pp.).

**France.** — A Ministerial Decree of February 15, 1939 appointing the members of the Advisory Committee for plant protection lays down that the Committee shall give its opinion on questions dealing with plant protection submitted to it by the Minister of Agriculture. It may submit to the Minister any proposals regarding its activities. The Committee is empowered to co-ordinate the research and experimental work carried out on the control of crop pests and shall determine the methods and products for general use. It shall advise assistance to be granted to agricultural organizations engaged in the control of crop pests as well as on the legal and regulation questions regarding crop protection.

By the same Ministerial Decree a Permanent Commission, presided over by the Director of Agriculture or his deputy, is constituted within the Committee. (*Bulletin de l'Office de Renseignements agricoles*, Paris, 1<sup>er</sup> mars 1939, année 1939, n° 5, p. III-III2).

**Italy.** — Royal Decree No. 2221 of July 29, 1938 lays down that the technical agricultural organizations for Libya and Italian East Africa are the Royal Agromomic Institute for Italian Africa [see this *Bulletin*, 1939, No. 4, p. 85], the agricultural Offices and the agricultural experiment Centres.

The control of the diseases and pests of crops is the province of the agricultural Offices which have the requisite means at their disposal.

The agricultural experiment Centres carry out scientific studies and research work dealing with the control of the diseases and pests of plants and agricultural products. (*Gazzetta Ufficiale del Regno d'Italia*, Roma, 15 marzo 1939, anno 80°, n. 63, pp. 1334-1337).

\* \* By Law No. 155 of January 5, 1939 the Royal Decree-Law No. 1781 of November 24, 1938 relative to the capture of sparrows with a view to protecting grain crops [see this *Bulletin*, 1939, No. 3, p. 56] is converted into Law. (*Ibid.*, 15 febbraio 1939, n. 38, p. 821).

\* \* Law No. 156 of January 5, 1939 converts into Law the Royal Decree-Law No. 1622 of September 5, 1938 relative to the protection of fruit trees [see this *Bulletin*, 1939, No. 2, pp. 32-34]. (*Ibid.*).

\* \* By Ministerial Decree of February 16, 1939, the control of the European corn borer (*Pyrausta nubilalis*) is compulsory in the provinces of Pesaro and Ancona, the method indicated in the Ministerial Decree of June 24, 1937 [see this *Bulletin*, 1937, No. 9, pp. 205-206] to be employed. (*Bollettino Ufficiale del Ministero dell'Agricoltura e delle Foreste*, Roma, 1<sup>o</sup> marzo 1939, anno XI, n. 5, pp. 505-506).

**Morocco (French Zone of).** — An Order of January 4, 1939 specifying the requirements regarding the export of onions from Morocco lays down, *inter alia*, that the onions exported must be free from parasites or disease. (*Bulletin Officiel*, Rabat, 20 janvier 1939, XXVIII<sup>e</sup> année, n<sup>o</sup> 1369, p. 70-71).

\* \* A second Order of the same date relative to melon exports prescribes that these fruits must be free from insects and disease. (*Ibid.*, p. 71-72).

**New Zealand.** — By Order of January 18, 1939, which may be cited as the Orchard and Garden Diseases Act Extension Order, 1939, the disease known as yellow dwarf disease (*Allium virus 1*) is declared to be a disease within the meaning of the Orchard and Garden Diseases Act, 1928. (*Serial Number 1939/2*, Wellington, 1939, 1 p.).

**The Netherlands.** — A Decree of February 21, 1939 specifies measures for the application of the Law of 1937 relative to the control of the diseases of flowering bulbs. (*Staatsblad van het Koninkrijk der Nederlanden*, 's-Gravenhage, den 28 Februari 1939, N<sup>o</sup> 653, blz. [1]-3).

**Southern Rhodesia.** — By Government Notice No 611 of December 16, 1938 concerning the regulations for the importation of plants, if 5 per cent. or more of any consignment of fruit is found to be infested with the apple codlin moth (*Cydia pomonella*) it shall be rejected, and reconsigned to the country of origin at the expense of the consignor or consignee or destroyed. If less than 5 per cent. is found to be so infested, the inspector may cause the whole consignment to be sorted and re-packed to his satisfaction. If the consignee or addressee or his agent is unable or unwilling to supply the necessary labour for this purpose, a fee of 3*d.* per tray or 1*s.* per bushel shall be charged for labour supplied. (*Colony of Southern Rhodesia Government Gazette*, Salisbury, December 16, 1938, Vol. XVI, No. 50, p. 951).

**Yugoslavia.** — Order No. 1129/II of January 11, 1939 gives a list of the countries to be considered in 1939 as being contaminated by wart disease of the potato (*Synchytrium endobioticum*), the Colorado beetle (*Leptinotarsa decemlineata*), the potato moth (*Phthorimaea operculella*), and the San José scale (*Aspidiotus perniciosus*). (*Službene Novine*, Beograd, 25. januara 1939, godina XXI, broj 18-IV, str. 37-38).

## DISCOVERIES AND CURRENT EVENTS \*

### Argentine Republic: Locust Invasion in 1938-39 †

The invasion of the South American locust (*Schistocerca paranensis*, Burm.) was less serious than in the preceding season, owing to the vigorous measures taken by the Crop Protection Service, in collaboration with various local institutions, and to the help of farmers, who took an active part in the destruction of this pest.

The first swarms were reported in the province of La Rioja at the beginning of June, 1938, and the movement spread insofar as it was favoured by the climate. They invaded the provinces of Salta, Santiago del Estero, Catamarca, Córdoba, San Luis, Santa Fé, and the Chaco Territory. Small swarms crossed the Río Paraná and invaded the provinces of Corrientes and Entre Ríos, where they laid their eggs, while in the north the Formosa Territory was invaded by a swarm from the south-west, which afterwards penetrated into Paraguay.

As in preceding years, the Crop Protection Service employed all the means at its disposal (flame-throwers, barriers, rollers, rakes, etc.). During the season successful experiments were made with dusts.

The following figures give an idea of the destruction of locusts in the various stages:—

Winged locusts . . . . .	2,549,365 kg.
Egg-pods . . . . .	390 »
' Mosquita ' . . . . .	19,823,826 »
' Saltona ' . . . . .	20,153,421 »
Total . . . . .	<u>42,527,002 kg.</u>

The largest quantity (34,297,526 kg.) was destroyed in the province of Santa Fé, where the invasion was most severe; next in order came the Chaco Territory, where 3,091,086 kg. of locusts were destroyed.

\* Under this and the next heading the countries are arranged in French alphabetical order.

† Communication from Mr. ABEL GOYTIA, Agricultural Engineer, Assistant Director of Plant Protection, Ministry of Agriculture, Buenos Aires, Argentine Republic.

Although it can hardly be said that a definite solution of the locust problem is to be found in the use of chemicals, there is no doubt that it was a very important factor in the destruction of the pest; that is to say, it leads to a considerable decrease in the damage caused each year by the adults, which are the most difficult to destroy. The chemicals used for dusting have the advantage of acting by direct contact, and they are harmless both to human beings and to cereal crops, so long as proper precautions are taken.

The destruction of locusts achieved, experimentally, by this method reached 33,673,000 kg., a very satisfactory figure; it will certainly become the surest and most rapid method in the anti-locust campaign and will tend to supersede the existing methods.

The above-mentioned experiments were carried out in only a small zone of the province of Santa Fé, owing to the scanty supply of apparatus; purchase of a large number is contemplated for the coming seasons, the type chosen being both powerful and manageable.

The following table shows the results obtained in the destruction of eggs and young locusts ('mosquita' and 'saltona' stages) effected in December, 1938.

Provinces and Territories	Eggs — Kg. (1)	'Mosquita'		'Saltona'	
		Kg. (2)	Ha. (2)	Kg. (2)	Ha. (2)
<b>Provinces: —</b>					
Santa Fé . . . . .	46,688	13,487,350	5,136	82,105,976	14,251
Corrientes . . . . .	—	1,791,182	1,086	6,801,734	4,438
Entre Rios . . . . .	7,742	6,400	3,650	1,450,200	3,608
Córdoba . . . . .	35,442	9,025,000	69,748	15,781,795	5,669
Salta . . . . .	40	19,200	—	35,400	—
San Luis . . . . .	11,309	777,600	483	4,627,800	—
Santiago del Estero . . . . .	—	65,150	—	546,600	—
<b>Territories: —</b>					
Formosa . . . . .	—	—	115	—	523
Chaco . . . . .	—	191,084	5,723	401,180	14,132
<b>Total . . .</b>	<b>101,221</b>	<b>25,362,986</b>	<b>85,941</b>	<b>111,750,685</b>	<b>42,621</b>

(1) Destruction by collection.

(2) Destruction by spraying and barriers.

(3) Area invaded.

### Eritrea and Amhara: Locust Movements \*

*Schistocerca gregaria*. This species was not reported in Eritrea during February, 1939.

\* Communication from Dr. LUIGI M. BOLOGNA, Chief of the Agricultural Bureau of Eritrea, Asmara, transmitted to the Institute by the Government of the Colony.

*Locusta migratoria migratorioides*. During the same month, neither egg-pods nor hatchings were noted in the territory of Eritrea. A few swarms of insignificant size were observed in western Tigray.

As compared with the previous months, the situation continues to improve. A few swarms flying in the direction of Dancalia were observed in the Uollo region.

Little damage has been caused.

\* \* \*

*Schistocerca gregaria*. No desert locusts were reported in Eritrea nor in Amhara during March, 1939.

*Locusta migratoria migratorioides*. During the first decade of March a swarm, coming from Lasta, was observed in Eritrea, chiefly in the Tigray zone, but it continued its flight towards Dancalia without stopping.

Neither egg-pods nor hatchings were noted in any district.

This being the general position, all the officers in charge of control operations have been recalled, although in some districts which are more subject to invasion, an observation service has been established.

In Amhara, towards March 20, swarms from Lasta were again reported; these have invaded the territories of Lanea and Liarza, and have destroyed the recently sown grain crops.

#### Greece: *Cerambyx dux*, a Pest of the Almond Tree \*

The island of Chios possesses about 500,000 almond trees, a good year's harvest amounting to 1,000,000 okas of almonds. The average production at present, however, is only 400,000 okas.

The value of this production is approximately 15 million drachmae per annum. Two thirds are exported to India and Egypt, the remainder being consumed in Greece.

In recent years, a xylophagous beetle has caused appreciable damage to the trees. The Benaki Phytopathological Institute has identified this insect as *Cerambyx dux*, Fald. The Chios Agricultural Service estimates the annual loss at 100,000 okas of almonds representing a value of 3,500,000 drachmae.

On the recommendation of the Benaki Phytopathological Institute, the Ministry of Agriculture has decided on the application of compulsory control measures in the island.

\* Communication from the official correspondent of the Institute, Professor Dr. C. A. ISAAKIDIS, Director of the Benaki Phytopathological Institute, Kiphissia-Athens, Greece.

### India: New Diseases Recorded in Burma during the Year 1938 \*

(1) *Cystopus candidus* (Pers.) Lév. on *Brassica campestris* at Maymyo and Kyaukse.

(2) *Pestalozzia* sp. on *Aleurites montana*, causing a leaf-spot disease at Hsum-Hsai.

(3) *Phytophthora* sp. on *Achras sapota*, causing a root-rot at Hmawbi.

(4) An eel-worm disease of paddy (*Oryza sativa*) known locally as 'Aket-phet' caused by *Anguillulina* sp.

The first symptom of the disease is the appearance of a flaccid brown or black stain at the point of attachment of the outermost leaf to its leaf-sheath. The discolouration, soon afterwards, extends both upwards and downwards slightly and as a result the leaf turns yellow and drops off. The symptoms then appear on the next full grown leaf which is also killed. The disease in this way, goes on infecting and killing the leaves upwards, till at the time of harvesting, the flag leaf only is left. As a result the yield is affected. The infection first took place when the plants were about a month old.

### Southern Rhodesia: Locust Invasion, 1932-1939 †

Monthly Report No. 75. February, 1939.

All reports refer to the red locust (*Nomadacris septemfasciata*, Serv.).

Winged swarms have been reported in the following districts, namely: Lomagundi, Darwin, Mazoe, Mtoko, Umtali, Bikita, Ndanga, Belingwe, and Gwanda.

Practically all these swarms were stated to be egg-laying.

Hoppers have hatched out in the districts of Lomagundi, Darwin, Mrewa, Mtoko, Inyanga, Umtali, Melsetter, Bikita, Charter, Victoria, Ndanga, Chibi, and Belingwe.

One instance of parasitisation of adult locusts with Dipterous maggots was recorded, and in another instance *Stomatorrhina* maggots were observed attacking the eggs.

Hatchings in various localities occurred about the middle of the month, that is about ten days to a fortnight earlier than in 1938. The hatchings are fully as heavy as occurred last year but there is nothing in the nature of a general outbreak.

The hoppers are being destroyed in all accessible localities.

\* Communication from the official correspondent of the Institute, Dr. I. N. SETH, B. Sc., Ph.D., D. I. C., Mycologist, Mandalay, Burma, India.

† Communication from the official correspondent of the Institute, Mr. RUPERT W. JACK, F. E. S. Chief Entomologist, Agricultural Laboratory, Department of Agriculture, Salisbury, Southern Rhodesia.

## LEGISLATIVE AND ADMINISTRATIVE MEASURES

**Germany.** — By Decree of January 10, 1939, the Minister of Agriculture has granted facilities for the import and transit of horticultural products from France, Belgium, Luxemburg and Switzerland, countries considered to be contaminated by the Colorado beetle [*Leptinotarsa decemlineata*]. This Decree repeats, with some modifications, and uniting them in one text, the provisions modifying the Decree of July 29, 1937 [see this *Bulletin*, 1937, No. 10, pp. 224-225], passed with a view to preventing the introduction of the Colorado beetle.

A list is given of the ornamental plants which may be imported throughout the year, living, and with roots, with or without adhering earth.

The aerial and fresh parts of the plants given in this list may be imported during the period from April 1 to November 14.

The bulbs of ornamental plants and the tubers of *Gloxinia* and *Begonia* may be imported at any period of the year.

Nursery plants are admitted during the period from November 15 to March 31, on condition that they are free from adhering soil and that the roots have been washed.

Celery stalks may be imported during the period from September 10 to November 14, and endive during the periods from April 1 to 30, and from October 15 to November 14.

Greenhouse cucumbers and melons may be introduced throughout the year, and asparagus, from November 15 to April 30. Consignments should be accompanied by a certificate testifying that the products in question were grown under glass.

Shoots of green asparagus may be imported during the period from November 15 to March 31.

All the above-mentioned consignments should be accompanied by a certificate granted by an officer of the Plant Protection Service; a sample copy is attached to this Decree. The consignments will also be inspected on entry by an expert of the Plant Protection Service.

The plants and parts of plants mentioned above may be allowed entry at any period of the year, if they form part of the hand luggage of a traveller, and are not intended for commercial purposes; on condition, however, that the frontier inspection has proved satisfactory.

The transit of the aforesaid plants and parts of plants and of fresh vegetables is authorized under the conditions laid down by the Decree of October 20, 1937 [see this *Bulletin*, 1938, No. 2, pp. 29-30].

All relative provisions previous to this Decree [see this *Bulletin*, 1938, No. 2, pp. 29-30; No. 6, p. 125; No. 7, 149; No. 9, pp. 193-194; 1939, No. 1, p. 5] are cancelled. (*Ämtliche Pflanzenschutzbestimmungen*, Berlin, 1. Februar 1939, Bd. XI, Nr. 1, S. 2-5).

\*\*\* By Decree of February 13, 1939, the Law of March 5, 1937 relative to the protection of cultivated plants [see this *Bulletin*, 1937, No. 7, pp. 149-150] has been extended to former Austria and the Sudeten region. (*Nachrichtenblatt für den Deutschen Pflanzenschutzdienst*, Berlin, Anfang April 1939, 19. Jahrg., Nr. 4, S. 35).

\*\*\* The new list of the communes infested by phylloxera [*Dactylosphaera vitifolia*] and those which are suspected or in danger of being contaminated is published in No. 49 (February 27, 1939) of the Official Journal (*Deutscher Reichsanzeiger und Preussischer Staatsanzeiger*). (*Ibid.*).

\*\*\* By Ministerial Order of March 3, 1939 based on the Decrees of March 28, 1929 and September 30, 1932 [see this *Bulletin*, 1929, No. 6, p. 83 and 1932, No. 12, p. 205] with view to preventing the introduction of the carnation leaf roller [*Tortrix pronubana*], imports of carnations (cut flowers) are allowed up to April 30, 1939. (*Ibid.*).

\*\*\* Ordonnance of March 31, 1939 relative to the trade in plants between Germany and former Austria, lays down that the new customs Law of March 20, 1939, having come into force on April 1, 1939, plants and any other goods which previously were only allowed to cross the frontier under certain conditions of a phytosanitary order, may, from this date, enter into Austria from Germany without any restriction. (*Ibid.*).

**Germany (Protectorate of Bohemia and Moravia).** — The Decree of March 21, 1939 relative to the customs system of the Protectorate of Bohemia and Moravia lays down that the regulations in force up to the present shall remain valid until further notice. (*Nachrichtenblatt für den Deutschen Pflanzenschutzdienst*, Berlin, Anfang April 1939, 19. Jahrg., Nr. 4, S. 35).

**England and Wales.** — With the object of preventing the introduction of the cherry fruit fly [*Rhagoletis cerasi*], the Importation of Raw Cherries Order of 1939, dated March 28, 1939, regulates the importation of cherries grown in Spain, France, Italy, Germany and Hungary during the 1939 season. (*Statutory Rules and Orders 1939*, No. 376, London, 1939, 5 pp.).

**Belgium.** — By Ministerial Decree of January 13, 1939, to prevent downy mildew (*Pseudoperonospora humuli*) hop fields are to be sprayed with preparations containing copper salts. The minimum is one treatment to be carried out during April and particularly when the spike-shaped shoots appear, a second treatment following the formation of the lateral shoots and a third during flowering.

The spike-shaped shoots are to be removed as soon as formed, and burnt.

In order to prevent the development and spread of aphids, contact insecticides are to be employed in controlling these insects as soon as they appear. (*Moniteur Belge*, Bruxelles, 23-24 janvier 1939, 109<sup>e</sup> année, n<sup>os</sup> 23-24, p. 343).

**Chile.** — Decree No. 90 of January 31, 1939 prohibits the use as seed of all wheats attacked by loose smut (*Ustilago tritici*). (*Diario Oficial de la República de Chile*, Santiago, 16 de febrero de 1939, año LXII, núm. 18. 294, págs. 564 y 565).

**Belgian Congo.** — Ordonnance No. 149-A. E. of November 28, 1938, regulating the export conditions for *Terminalia superba* unbarked timber, requires *inter alia* that the timber should be free from puncturing (holes or tunnelling caused by the larvae of different insects), rot, scald (special type of rot, less advanced stage), etc. (*Bulletin Administratif du Congo Belge*, Léopoldville-Kalina, 10 décembre 1938, 27<sup>me</sup> année, n° 23, p. [752]-754).

**Egypt.** — By two Orders of February 21, 1939, *Laphygma exigua* and *Agrotis ypsilon* are declared cotton pests. (*Journal Officiel du Gouvernement Egyptien*, Le Caire, 27 février 1939, 66<sup>me</sup> année, n° 21, p. 2).

\*\*\* An Order of March 22, 1939 declares *Lecanium acuminatum* a noxious pest of fruit trees.

The markaz of Zagazig is declared infested with this scale insect.

Transport, by any means, of mango trees, parts of the plant and fruits, from the infested area to any other district is prohibited. The sale or putting up for sale of plants, parts of plants and fruits attacked by the aforesaid insect is prohibited throughout the country. (*Ibid.*, 6 avril 1939, n° 35, p. 7-8).

\*\*\* By another Order of the same date, *Aulacaspis cinnamomi* var *mangiferae* is also declared harmful to fruit trees.

The markaz of Beni Mazar, moudirieh of Minieh, is declared infested with this scale insect.

Transport, by any means, of mango plants, parts of plants and fruits, from the infested area to any other part of the country, is prohibited. The sale or putting up for sale of infested plants, parts of plants and fruits is prohibited. (*Ibid.*, p. 8).

**France.** — A Ministerial Decree of January 12, 1939 determines the distribution among the different agricultural areas, of the importers and exporters of agricultural products of plant origin, registered for 1939 by the Phytopathological Service. (*Bulletin de l'Office de Renseignements agricoles*, Paris, 1<sup>er</sup> février 1939, année 1939, n° 3, p. 58-59).

\*\*\* A Ministerial Decree of January 26, 1939 authorizes the sale and use of certain cyanide products (Zyklon B, Cyanogas A, Cyanogas G, granulated Cyanogas), to be utilized for fumigation in agriculture, the disinfection of living plants, soils, greenhouses and industrial premises, under the conditions established by the Ministerial Decree of July 20, 1938 [see this *Bulletin*, 1938, No. 12, p. 271-272]. (*Ibid.*, p. 60).

\*\*\* A second Ministerial Decree of the same date authorizes the sale and use of certain preparations (the arsenical and cupric powder A. C. F. S., 'Supremacy' brand, and cuprocalsarine) containing calcium arsenate, in the form of powder mixed with denaturants, for the treatment of potatoes under the conditions fixed by the Ministerial Decree of August 1, 1938, [see this *Bulletin*, 1938, No. 12, p. 272]. (*Ibid.*, p. 61).

\*\*\* By Law of March 6, 1939, the Minister of Agriculture, is authorized, as an exceptional measure, to grant a lump sum for each department for the purpose of assisting the farmers of those districts where the autumn and winter forage plants, which are essential for the maintenance of live-stock, were destroyed by the frosts of December, 1938, to purchase waste wheat. (*Ibid.*, 15 mars 1939, n° 6, p. [121]-122).

\*\*\* By another Law of the same date, the farmers who can prove that they purchased seed wheat from authorized cooperative associations or merchants, during the period from the December, 1938 frosts to April 20, 1939, for the purpose of re-sowing their fields damaged by the said frosts, will be allowed, as a special claim, an exemption of 22 fr. per quintal on the amount of the special resorption quota, according to the quantity of wheat purchased. (*Ibid.*, p. 122).

\*\*\* A Ministerial Decree of April 15, 1939 delimits the zones contaminated by the Colorado beetle [*Leptinotarsa decemlineata*] and the protection zones. (*Journal Officiel de la République française*, Paris, 27 avril 1939, LXXI<sup>e</sup> année, n° 100, p. 5429-5432).

**Italy.** — By Ministerial Decree of February 2, 1939, the export of copper sulphate is prohibited. (*Gazzetta Ufficiale del Regno d'Italia*, Roma, 8 febbraio 1939, anno 80<sup>o</sup>, n. 32, p. 677).

\*\*\* By Ministerial Decree of March 6, 1939 the application of the exchange duty at the reduced rate of 0.75 per cent. is extended from March 20, 1939 to the parasiticides 'Cuprital arsenicato' and 'Arsenial'. (*Ibid.*, Roma, 28 marzo 1939, n. 75, p. 1531).

\*\*\* By Ministerial Decree of March 13, 1939, the control of the bean broomrape [*Orobanche crenata*], by collecting and destroying the parasite, has been made compulsory in the Province of Ragusa. (*Bollettino Ufficiale del Ministero dell'Agricoltura e delle Foreste*, Roma, 21 aprile 1939, anno XI, n. 29, pp. 852-853).

\*\*\* By Ministerial Decree of March 15, 1939, the control of the cockchafer (*Melolontha melolontha*), by collecting and destroying the adults, has been made compulsory in the province of Belluno. (*Ibid.*, pp. 853-854).

**Morocco (French Zone of).** — An Order of February 2, 1939 authorizes the use of mercury salts and organic mercurial compounds for soil and seed disinfection — not for any grain or seeds employed in human and animal nutrition — and specifies the precautions to be taken. (*Bulletin Officiel*, Rabat, 10 février 1939, XXVIII<sup>e</sup> année, n° 1372, p. 176-177).

\*\*\* A second Order of the same date authorizes the establishment of a syndical association for the control of plant parasites to be known as the ' Association syndicale de lutte contre les parasites des plantes du Bas-Sebou '. (*Ibid.*, p. 177).

\*\*\* An Order of February 15, 1939 proposes an enquiry with regard to the establishment at the Petitjean civil control post of a syndical association for the control of plant pests, to be called the Petitjean Association. (*Ibid.* 3 mars 1939, n° 1375, p. 241).

\*\*\* An Order of February 17, 1939 regulates the use of hydrocyanic acid gas and cyanides for the control of plant parasites. (*Ibid.*, p. 241-242).

\*\*\* An Order of February 17, 1939 authorizes the destruction of wild boars causing heavy damage to crops in the territory of the Kelâa-des Slès civil control post, Fez region. (*Ibid.*, p. 243).

\*\*\* An Order of March 10, 1939 authorizes steps with regard to the establishment of a syndical association for the control of plant pests, to be known as the ' Association syndicale de lutte contre les parasites des plantes de la vallée de l'Ouerrha '. (*Ibid.*, 24 mars 1939, n° 1378, p. 362).

\*\*\* The Vizirial Decree of March 29, 1929 (7 safar 1358) supplements the Vizirial Decree of March 17, 1936 (23 hija 1354) giving the list of pests in regard to which syndical associations for control may be set up [see this *Bulletin*, 1936, No. 8, p. 179], by adding the olive fly (*Dacus oleae*). (*Ibid.*, 28 avril 1939, n° 1383, p. 552).

\*\*\* Four Orders of April 18, 1939 relative to the inspection of artichokes, potatoes, carrots and French beans for export prescribe, *inter alia*, that these products must be free from disease or insect attack. (*Ibid.*, 5 mai 1939, n° 1384, p. 625-627).

**Switzerland (Canton of Vaud).** — An Order of February 1, 1938 regulates the sale of arsenical products or other poisonous substances for use exclusively in arboriculture, wine-growing, horticulture and agriculture (vegetables excepted). (*Recueil des lois, décrets, arrêtés et autres actes du Gouvernement du Canton de Vaud*, Lausanne, 1939, tome CXXXV, 1938, p. 39-41).

\*\*\* A Decree of May 17, 1938 abolishes, for 1938 and 1939, the landowners' tax for phylloxera insurance. (*Ibid.*, p. 145).

\*\*\* An Order of October 28, 1938 regulates: (a) the use of hydrocyanic acid gas and substances which evolve this gas, when employed for destroying rodents or insects, disinfecting property or any other object; (b) the utilization of rat poisons. (*Ibid.*, p. 177-179).

[The author suggests the drawing up of an international register of fungicides, insecticides, parasiticides, herbicides, etc. which, according to the advice of the Phytopathological Services of the different countries, are recognized as being effective in controlling determined crop diseases and pests, surely harmless to plants and which may therefore be safely recommended.  
In practise, this register would aim to keep down the trade of preparations of doubtful value or even harmful to plants].
